# ILLUSTRATIVE PROJECTIONS OF THE POPULATION OF STATES 1970 TO 1985

## INTRODUCTION

This report presents alternative series of projections of the population of States, from 1970 to 1985, taking into account data on interstate migration from the 1960 Census, as well as the estimated changes in State population that have occurred since 1960. They are consistent with the most recent national population projections published last year in Current Population Reports, Series P-25, No. 286, "Projections of the Population of the United States, by Age and Sex: 1964 to 1985," published July 1964.<sup>1</sup>

The projections on total population shown in tables 1 and 2, by regions, divisions, and States, differ slightly from those published earlier in report No. 301 of this series (Advance Report, published February 26, 1965). These minor differences are the results of modifications in the derivation of the age-sex-color cross-classification. The general pattern of State population redistribution projected is the same as in the Advance Report. In addition to projections of total population, data are shown for broad age-groups, sex, and color. Projections are shown for quinquennial dates only (except in selected appendix tables).

These projections are based on a number of reasonable alternative assumptions concerning the redistribution of population through interstate migration, as well as on alternative assumptions concerning future national fertility. (Only one assumption concerning future mortality is used.) It is not claimed that the assumptions will demarcate the range within which either fertility or interstate migration are almost certain to fall; furthermore, the population projections are not intended as predictions, but rather as indications of the population distributions that would develop on the basis of these assumptions. One of these assumptions is the continuation throughout the period of the interstate migration pattern of the recent past. The choice of assumptions on interstate migration (which, in State projections, is the variable with the highest degree of uncertainty) was dictated by the reasonableness and logic of the underlying hypotheses, by the desire to make maximum use of the detailed

data on interstate migration from the 1960 Census, and by the fact that the assumptions chosen can be applied uniformly to all States.

Unlike the procedure in the case of current population estimates, the choice of method was not made on the basis of the relative accuracy of the various methods in the past.<sup>2</sup> More important than the particular method chosen is the choice of assumptions. Since the usual assumptions provide for continuation or gradual change in demographic trends, an assumption may produce projections which parallel current trends very closely for a while, but then fare poorly in a period characterized by an abrupt reversal of a trend. New procedures for developing projections are also brought about by the availability of new kinds of pertinent data.

The method used here, the component method, makes separate projections for each of the components of population change. One advantage of this method, as contrasted with, for example, the ratio method, is that it takes advantage of the fact that some of the components are likely to change relatively little. This seems to be the situation with respect to survival rates. More direct use can be made of national projections of mortality, fertility, and net immigration from abroad. The component of interstate migration still remains the major source of uncertainty and will very probably make the major contribution to the difference between the projected and actual population growth. Furthermore, interstate migration is likely to be more important in influencing the rate of growth than fertility or mortality.

The projections are based on the assumption that there will be no major war, severe economic depression, or other similar catastrophe. The projections are generally designed to be consistent with assumptions of continued high economic activity nationally and, for at least one of the series, of the preservation of recent differentials in economic activity among the States. The projections incorporating "migration series I" assume the continuation of past trends and patterns of population redistribution through interstate migration. Although the specific relationship

<sup>1</sup> Revisions of these national projections are now in process and are planned for publication shortly in Series P-25.

<sup>2</sup> An evaluation of the relative accuracy of past projections of States is described in: Helen R. White, "Empirical Study of The Accuracy of Selected Methods of Projecting State Population," Journal of the American Statistical Association, Vol. 49, No. 267, September 1954, pp. 480-499.

between the size of migration streams and economic conditions is not known, it is generally believed that interstate migration movements are significantly affected by differential economic opportunities and that any drastic changes in the economic advantages of one State over another will have substantial impact on the future size of migration streams and even on the direction of net migration for the affected States.<sup>3</sup> Furthermore, no attempt is made to assess the possible regional impact of substantial reduction (or increase) in the level or pattern of defense spending or of such specialized regional programs as Appalachia, or any other regional development plans still forthcoming. The possible impact on migration trends of recent defense developments resulting from the greater American involvement in Viet-Nam, for example, is not explicitly or implicitly taken into account.

Basically, the projections start with estimates of total population of States for July 1, 1964, published in report No. 289 of this series.<sup>4</sup> The 1964 estimates are carried forward to each projection date on the basis of separate projections of each of the components of change. Operationally the computations start with the April 1, 1960, Census data, by State, by age, sex, and color, and are carried forward on the basis of separate projections of each of the components of change, also by age, sex, and color. They have been forced into agreement with estimates of the total population of States for July 1, 1964. The projections relate to the total resident population, that is, the civilian resident population plus members of the Armed Forces stationed in each area in the United States. The Armed Forces overseas are excluded. Thus, the sums of States' figures shown here do not always agree with those given in the national population projections report No. 286 because of differences in the population covered.

#### INDICATED CHANGES<sup>5</sup>

Total population.--Between 1965 and 1985, the population of the United States as a whole, on the

<sup>3</sup> The underlying State differentials in economic activity implied by converging interstate migration rates assumed under "migration Series II" cannot be explicitly stated. It is to be expected, however, that such changes in future migration trends may be brought about, in part, by changes in the relative competitive position of States, with some equalization of economic opportunities among States.

<sup>4</sup> Revised estimates of State population for 1964 and provisional estimates for 1965, have become available since these projections have been completed. They are published in report No. 324 of this series. See section below on "Related Reports."

basis of the most recent published projections, would increase by about 50 to 80 million. Although virtually all States would share in this projected national gain, there would be substantial variation among the States in rate of growth. In general, the factors underlying the specific assumptions of future population distribution used in these projections tend to produce patterns of growth in the short term similar to those of the recent past, but with some moderation. States which are projected to grow at rates well in excess of the national average, such as California, Arizona, Nevada, New Mexico, and Florida, are the same as those which in recent past years have had the most rapid rates of increase. Under the interstate migration patterns and levels assumed here, each of these States is projected to grow at twice the national average.

In terms of absolute growth, California is projected to outstrip by far all other States, with an estimated increase of from 10 to 14 million persons in the next 20 years. The ranges in population growth projected for some other States are: Florida, New York, and Texas--3 to 5 million; Ohio, Illinois, and New Jersey--2 to 3 million. By 1985, West Virginia is projected to have about the same population as currently in the State, but may, depending upon the migration assumption, exceed its 1960 population level of 1.9 million. The projections indicate that, even with the continuation of recent out-migration rates, the population decline in this State would continue only to 1970-75. Population losses could well cease after that period, as the result of natural increase exceeding net out-migration.<sup>6</sup>

<sup>5</sup> The discussion of indicated changes in State population relates to Series I-B mainly. In general terms, however, the overall projected pattern of growth for most of the projection period is fairly consistent among the four series using migration assumptions I or II. This discussion does not relate to the "zero migration" assumption (Series III) shown in the appendix tables, since the projected figures under that assumption are quite different.

<sup>6</sup> West Virginia illustrates a situation where the long-range projections shown here need to be interpreted carefully and assessed in the light of such impending developments as the new Appalachia program, which may have an important impact on future migration trends. Historically, West Virginia has experienced net out-migration during most of the present century, with heavy losses in the two most recent decades. If there were to be no further net out-migration from West Virginia, then, by 1975, the population would reach its 1950 high of about two million. By 1985, under the assumption of a continuing net interstate migration balance of zero (and Series B fertility), the population of the State would reach 2.3 million.

For most States (and regions), the projected pattern of population change over the next 20 years will be about the same during the first and second decades (1965-75 and 1975-85), although some moderation of growth differentials would occur in the latter decade of the projection period. State growth rates that are initially well above the national average tend to decelerate slightly during the projection period, whereas rates initially well below average would tend to accelerate. Comparative average annual rates of growth of the States under the various assumptions, over selected time periods, are shown in table 3. Graphic illustrations of past and projected trends in average annual rates of growth are shown in figure 2 (which is based on Series I-B).

Age composition.--Important shifts in the age structure of the national population are expected in the future as the result of past trends in birth rates. The first wave of the postwar surge of births, starting in 1946 is just beginning to enter the college-age group; and, as a consequence, this group will grow substantially more rapidly than other age groups in the next several years. Between now and 1985, the most rapidly growing groups are expected to be those of college age (18 to 24) and those in young adulthood (25 to 34).

The unusual changes in the pattern of births in the past 30 to 40 years will produce some imbalances in the labor force supply. By 1975, for example, there will be fewer persons 35 to 44 years of age, the age group which is perhaps the main reservoir for new, young, executive talent, than there are in the group at present. At the same time, a substantial supply of young labor-force entrants will be forthcoming. Persons now 25 to 34 years of age represent the group born during the low birth-rate period of the 1930's.

These people will be 35 to 44 years of age by 1975 and 45 to 54 years of age by 1985. Thus, the deficit in the 35 to 44 group in 1975 indicated earlier will shift to the 45 to 54 group in 1985. For the 35 to 54 year group as a whole, however, little change in the population is expected between now and 1975, but increases are expected by 1985. A detailed discussion of changes in the national age-sex structure of the population, particularly as related to the important functional age groups (school-age population, population in the main working ages, and the elderly) is given in Series P-25, No. 286, pages 4 to 10.

State changes in age composition during the projection period will, to a large extent, parallel those at the national level, but with some important State variations taking place as a result of net interstate migration. State differentials in natural increase should have relatively little effect, however. The heavy increase projected nationally for the college-age group and the younger working ages will generally prevail throughout the States. Inasmuch as these age groups contribute heavily to interstate migrants, higher than average growth rates are projected for those States mentioned earlier (Arizona, California, and Florida) as likely to have the most rapid growth of total population. Substantially lower than average rates of growth are projected, with some losses, for all age groups in States with heavy out-migration, such as West Virginia and Pennsylvania.

The significant role played by net interstate migration in determining future population distribution and the uncertainty of the volume and direction of such migration certainly preclude any precise statements as to the amount of change forthcoming in broad age groups for each of the States. In general, however, it appears safe to presume that States experiencing higher than

average growth rates overall will also experience higher than average rates of growth in the age groups showing rapid growth nationally. States with overall rates of growth well below national averages (those with heavy rates of net out-migration) may experience only small changes in these age groups, as opposed to the expected heavy national average increases. The projected population by broad age groups and the corresponding percents of increase are given in table 5. Table A above shows illustrative figures on comparative State and national rates of growth, by age, for selected States grouped into three broad categories--those with substantially higher rates of growth than national average, those with average growth rates, and those with rates substantially below the national average.

#### METHODOLOGY

As stated earlier, the projections were prepared by a procedure in which each of the components of population change--that is, births, deaths, and net migration--was projected separately. The procedure involves starting with the 1960 population, by age, sex, and color, and carrying the population forward by 5-year periods to each projection date on the basis of assumptions concerning future births, deaths, and net interstate migration. Each of the components is also carried forward separately, by age, sex, and color. Alternative assumptions regarding some of the components are prepared in order to provide reasonable ranges concerning future changes in State population.

All told, four main series of projections are shown--that is, two assumptions concerning future interstate migration combined with two levels of fertility, labelled Series I-B, I-D, II-B, and II-D. The Roman numerals relate to the migration assumption; the letters designate the national fertility series incorporated in the projections. The underlying assumptions for each series can be broadly summarized as follows:

Series	Interstate migration assumption	National fertility assumption <sup>7</sup>
I-B...	Gross migration rates of the 1955-60 period will continue throughout projection period.	Very moderate decline from present levels.
I-D...	Same as I-B	Substantial drop from present levels.
II-B..	Convergence of the 1955-60 gross migration rates during the projection period.	Same as I-B
II-D..	Same as II-B	Same as I-D

The methods and assumptions used to derive the various projection series are described below.

Projections of births.--Even at the national level, the number of births for the future years cannot be projected with a high degree of certainty. Because of the wide range of reasonable possibilities in the future course of fertility, the national population projections report (Series P-25, No. 286), includes a number of alternative fertility levels based on different assumptions. Four principal series were developed to describe the future course of fertility. In the projection of births for a given State for future years, the elements of uncertainty existing at the national level still prevail; nonetheless, in terms of overall fertility, the factors determining changes in future national fertility are not believed to have an appreciable impact on the fertility differentials already existing among the States. Consequently, the approach here for State projections of fertility is not one of determining the future course of fertility in each specific State, but rather, of distributing the previously projected national number of births to the State on the basis of some reasonable criteria. The main elements used to distribute the national projections of the number of births are: (a) the size of the female population of each State in the childbearing ages, and (b) the State's recent level of overall fertility (births per 1,000 women 15 to 44 years old) in relation to national levels.

For present purposes, two of the national series of fertility projections, Series B and Series D, were chosen. Fertility rates (defined here as the number of births per 1,000 women in the ages 15 to 44 years) for each State, were computed for a 3-year period centered on April 1, 1960. The corresponding national rate for that period was also computed. Using the 1960 relationship of the State rates to the national rates (referred to hereafter as the State-national ratios) as starting points, it was assumed that the State-national ratios would reach unity in 50 years. It is assumed, in effect, that the factors producing State differences in fertility will gradually disappear and that, in approximately 50 years, the fertility rates for all States will be equal to the national rate.

The State-national ratios for the years intermediate between 1960 and 2010 were obtained by linear interpolation. State fertility rates for each projection period, 1960-65 to 1980-85, were derived by applying the projected State-national ratios to the previously computed national

<sup>7</sup> The national projections now in preparation will alter the fertility assumptions somewhat and will lower Series D considerably in the short run. However, the basic assumptions and methodology have not been greatly changed so that trends in births will be much the same as assumed in this report.

fertility rates for these periods (Series B and Series D, separately). These projected fertility rates for States, multiplied by the projected number of females 15 to 44 years of age, yield projections of the number of births for each State for each period. The projected number of females 15 to 44 years old for each State had been derived as part of another stage of the projections, by carrying forward the 1960 population rates by age, using specific mortality and gross interstate migration rates. Births projected for each State for each 5-year period were then summed and adjusted to add to the national total.

The computations described were carried through for the white and nonwhite population separately. For this purpose, a special set of national fertility rates for white and nonwhite populations was computed, based on the general assumption that the white-nonwhite differentials in fertility would be reduced by one-half during the next 50 years.<sup>8</sup> The resulting fertility rates by color provided the national figures needed to compute the number of white and nonwhite births for each State. Adjustments to national totals, however, were not made for white and nonwhite separately, but rather for total male births and total female births, with the white and nonwhite births for each sex absorbing a proportionate share.

The national fertility rates by color used here as bases in computing the State rates are as follows:

Table B.--PROJECTED FERTILITY RATES, BY COLOR: 1960-1965 TO 1980-1985  
(Average annual number of births per 1,000 females 15 to 44 years of age, for middate of each period)

Period	Series B			Series D		
	All classes	White	Non-white	All classes	White	Non-white
1960-65.....	114.9	109.4	155.1	110.3	105.1	148.8
1965-70.....	112.0	106.4	151.4	99.6	94.6	134.6
1970-75.....	115.8	110.1	153.9	97.9	93.0	130.1
1975-80.....	117.6	111.9	153.8	96.4	91.8	126.1
1980-85.....	114.6	109.1	147.4	92.4	88.0	118.8

Projections of deaths.--One set of age-sex-color specific mortality rates was used for all States for all series in the projections. The rates, by age and sex, were the same as those used

<sup>8</sup> These figures were computed specifically as a means of obtaining births by color by States for this report. The new projections referred to previously will include color detail for the first time. The assumptions respecting color employed there will be quite similar to those used for the State projections, but will differ somewhat in the methodological details, so that comparable projections will not be altogether consistent.

in the national population projections. These were based on the higher of two sets of mortality projections, designated "low" and "high," prepared in 1957 by the Division of the Actuary, Social Security Administration. A detailed discussion of the derivation of the national mortality projections and the underlying logic in the selection of the specific assumptions is given on page 24 of the report on national population projections, Series P-25, No. 286.

Since national mortality rates by color were not used in preparing report No. 286, they had to be projected for the present report. The initial age-sex-color survival rates were those from the 1962 United States Abridged Life Tables. It was assumed, for the purposes of these projections that the 1962 white-nonwhite differentials gradually will be reduced and that the differentials will disappear entirely in about 100 years. It was further assumed that the reduction in white-nonwhite mortality differentials would take place linearly starting from the 1960-65 period.

The projections of deaths by age, sex, and color, using the national mortality rates and the especially derived white-nonwhite rates, were adjusted by age and sex for each 5-year period to the overall number of deaths from the national projections report. The same adjustment factors were applied to white and nonwhite deaths within each age-sex group. In general, the overall adjustments were quite small, as expected, since the specific age-sex mortality rates used for the States were the same as those used at the national level.

The use of only one set of age-sex-color specific mortality rates is not intended to deny that State differences in mortality exist. It is believed, however, that allowing for the actual State differences in mortality would have very little impact on the present population projections.

Projections of interstate migration

1. General.--The method used to develop estimates of future net interstate migration for each State represents an important departure from the procedures used in the past. In a number of earlier reports of the Bureau of the Census presenting projections of State population, in which a component procedure was used, assumptions concerning future interstate migration were expressed in terms of "net migration," stated either in terms of rates or absolute levels.<sup>9</sup>

The use of net migration rates requires a choice of type of rate. The manner in which the rates are used suggests that the rates should represent probabilities in which the population exposed to the risk of migration is used as the base

<sup>9</sup> See Series P-25, Nos. 160 and 110.

in determining the rates. There is a problem in expressing such a rate for net in-migration. The conventional procedure has been to use as the base the population at the beginning of the period for each State affected, regardless of whether it had a net in- or out-migration. Another major problem in the use of net migration rates is that if one assumes the continuation of past trends in the rates, in-migration States automatically receive larger and larger numbers of net in-migrants, while out-migration States contribute fewer and fewer out-migrants, as the base population of specific age groups in the latter States becomes smaller as a result of out-migration. The inconsistency of the situation is obvious, since, under these circumstances, the net in-migrants and the net out-migrants become heavily unbalanced, and the computed net migrations require progressively larger adjustments to make them balance out to zero (or to a national control total representing net immigration from abroad).

These considerations suggest the use of gross figures on in- and out-migration starting with out-migration rates. Pertinent migration statistics are available by States for only three periods, the most recent being the 1955-60 period. In the 1960 Census, a specific question was asked on the State of residence of persons in 1955, thus providing information for all States on in-migrants and out-migrants, by age, sex, and color.

The projections of future interstate migration used here were developed in terms of out-migration and in-migration separately, State by State, using the pattern of the gross interstate movements of the 1955-60 period. Under this procedure, the sum total of net interstate migration for all States is zero. Separate computations were made for net immigration from abroad.

Unlike assumptions of continuing net migration rates, this procedure avoids inevitable automatic increases in the number of net migrants of gaining States. As the population base of a State grows in any age-sex-color group, it contributes more persons to the migration pool. The number of in-migrants it receives, however, represents a proportion of the total migration pool and is unaffected, or affected very little, by the changing size of its population. As its out-migration share grows, its net migration tends to become smaller.

Annual data from the Current Population Survey for the past 15 years show marked stability in the overall national rate of interstate migration. The annual rate of interstate migration has varied within very narrow bounds, averaging about 3.3 percent per year.<sup>10</sup>

<sup>10</sup> Current Population Reports, Series P-20, No. 141.

In the projections according to assumption I--discussed in paragraph (2) below--the rate of interstate migration for each 5-year period averages out to about 3.3 percent annually. This constancy is to be expected, since the projections assume a continuation of the age-sex-color migration rates of the 1955-60 period. The changing age-sex-color composition of the various States does not have an appreciable impact on the overall rate of interstate migration. Even under Series II, discussed in paragraph (3) below, however, where the migration rates by States are assumed to change, the national interstate migration rate remains similar to that of Series I.

2. Migration Series I.--In Series I, it is assumed that the gross out-migration rates and the in-migration distributions of the 1955-60 period will remain constant throughout the projection period. The gross out-migration rates, by age, sex, and color, were used to derive the total number of out-migrants, for each State, for each 5-year period, throughout the projection period. The numbers of out-migrants from all States were summed to a national total for each 5-year period and distributed as in-migrants to States on the basis of the percentage distribution of in-migrants of the 1955-60 period. The difference between a State's contribution to the gross number of out-migrants and the number it receives as in-migrants, represents net interstate migration for the State. The computations were carried through separately, by age, sex, and color, and hence reflect the changing age-sex-color composition of the States population. (As stated, separate computations were made for net immigration from abroad.)

3. Migration Series II.--In Series II, it is assumed that the gross out-migration rates will converge toward national levels. At the same time it is assumed that the in-migration distribution will converge toward the State population distribution. In effect, then, whereas Series I holds the 1955-1960 rates constant, Series II assumes a trend in the rates. In seeking an alternative assumption, consideration was given to the possible ways in which out-migration rates and in-migration distributions could be modified. In reviewing the various possibilities, it was concluded from the historical evidence, as indicated earlier, that there is little prospect that the national rate of interstate migration will dwindle away in the future. Some equilibrium in net migration may be reached, however, if economic opportunities and other social and economic differentials among the States tend toward equality.

Thus, the assumption adopted for Series II is that State migration differentials will gradually be reduced, and that at some point in time

(approximately 50 years), the number of persons migrating from a State will be offset by an equal number of persons moving into the State, thus providing zero net migration for each State. This alternative migration assumption requires some change from current gross migration rates during the projection period.

To achieve this equilibrium of migration, it was assumed that at the terminal point, 50 years hence, the total number of out-migrants and in-migrants will each be distributed in proportion to the population of the States. Thus, a State with 10 percent of the population of the country will contribute 10 percent of the total interstate migration pool (out-migrants) and receive in turn, 10 percent of the migration pool as in-migrants.

Operationally, the rates for Series II were obtained by interpolating between (1) the 1955-60 out-migration rates by age, sex, and color for each State; and (2) national interstate rates by age, sex, and color, so that by the period 2005-2010, the out-migration rates for all States are equal to the national averages. Interpolated values for intervening periods are then a function of time. For example, convergence becomes halfway complete in half the time, in other words after 25 years.

Symbolically, the series for a specific age-sex-color group is derived as follows:

- $M_i$  = out-migration rate in State  $i$
  - $P_i$  = population at beginning of period in State  $i$
  - $\sum P_i$  = total population of the United States (sum of States) at beginning of period
  - $M_i P_i$  = number of out-migrants from State  $i$  during specific quinquennium.
- Then:
- $\sum M_i P_i$  = sum of out-migrants from all States for specific period
  - $\frac{\sum M_i P_i}{\sum P_i}$  = national interstate migration rate for period.

The assumption under Series II is that in 50 years, for each State,

$$\frac{M_i P_i}{\sum M_i P_i} = \frac{P_i}{\sum P_i}$$

$$\text{Thus, } M_i = \frac{\sum M_i P_i}{\sum P_i}$$

For any given 5-year period, the out-migration rate is derived from  $k(M_i) + (1 - k) \frac{\sum M_i P_i}{\sum P_i}$ ,

where  $k$  is computed proportionate to time. To illustrate, for the 1960-65 period, ( $k$ ) equals 0.95; in 1980-85, ( $k$ ) equals 0.55. Thus, by the year 2010, ( $k$ ) equals 0 and the State out-migration rate is equal to the national rate.<sup>11</sup>

Similar computations were carried through for the in-migration distributions; that is, for each period of time, the interpolation was made between the percentage of in-migrants that a State received in the 1955-60 period and the percentage of migrants it would receive proportionate to its population. Here, too, the interpolations were made proportionate to time, so that in 50 years the percentage it would receive as in-migrants from the interstate migration pool would be the same as its share of the national population.

Migration assumption II, as compared to assumption I, has a more moderating effect on the projected redistribution of population. States growing well above the national average are slowed down in their rates of growth as gains through migration exchanges with other States are reduced. Correspondingly, States with heavy out-migration begin to receive migrants at a faster pace because of reduction in their contribution of out-migrants and of increases in their share of in-migrants. Although under migration assumption I such changes in population redistribution also occur, the effect under Series II is substantially greater.

4. Net immigration from abroad.--Net immigration was allocated to the States separately, using as an overall total the level established in the national population projections--that is 300,000 per year. The distribution to States is made on the basis of the 1960 State of residence of the foreign-born population reported in the 1960 Census as living abroad in 1955. The amount of net immigration allocated to each State for each 5-year period after July 1965 is shown in appendix table A-6.

5. Adjustment of migration rates.--As stated, data from the 1960 Census on interstate migration of the 1955-60 period were used to derive estimates of migration for the projection period. The gross migration rates of the 1955-60 period, however, were modified in two important respects, as follows:

a. Adjustment for military movement.--

The basic 1955-60 migration data include both civilian and military interstate migration. Because the migration rates around military ages are unusually high and States with large military installations gain migrants at the expense of States with little or no military personnel, an assumption of the continuation of such migration rates for extended periods leads to unreasonable results in some instances. Specifically, the number of males becomes increasingly larger (compared to the number of

<sup>11</sup>  $k(M_i) + (1 - k) \frac{\sum M_i P_i}{\sum P_i} = \frac{\sum M_i P_i}{\sum P_i}$  when  $k = 0$ .

females) in those States with the large military installations. Such results are inconsistent with the assumptions underlying the basic projections, that is, the assumption of no significant changes in the size and distribution of the Armed Forces in the United States over the projection period.

In order to reduce the impact of such movements, the migration data have been modified to exclude, to as large an extent as possible, gross movements of military personnel. In effect, the 1955-60 rates were modified to reflect only civilian migration, with estimates of the Armed Forces movements handled separately in the procedure.<sup>12</sup> Although this procedure had, in general, little impact on the overall total population of States, it does have significant impact on the age composition of males, particularly around the military ages, in those States with large military installations. Although the conversion of the migration rates of the total population to the civilian population is somewhat imperfect because of the lack of necessary information required to make such adjustments, it is believed that the modification significantly improved the projections for those ages and States where such adjustments were important.

b. Adjustments to make rates consistent with current estimates.—It was also necessary to modify the 1955-60 rates for the short run in order to take account of population changes, mainly due to net migration, that have occurred since 1960. Estimates of net migration for States for the period from 1960 to date have been developed in connection with the Census Bureau's regular program of annual State estimates. The latest current estimates available at the time these projections were undertaken were those for 1963 (and provisionally for 1964) published in report No. 289 of this series.

The adjustment was accomplished by first computing "projections" of net interstate migration for the 1960-65 period using the 1955-60

<sup>12</sup> It was assumed that the number of Armed Forces, at home and abroad, would remain constant at approximately the 1963 level. Persons entering the Armed Forces were distributed, by age, to States of pre-service residence on the basis of the 1963 State population distribution. They were assigned to State of duty station using the 1963 State of station distribution of the Armed Forces. This procedure leads to a net movement of zero for each State between military and civilian population, as assumed in the projections. Age by age, there is substantial differential movement among the States since most entries into the Armed Forces occur at ages 15 to 24 years and most returns to civilian life occur at later ages.

migration rates (as in assumption I) and then comparing these estimates with independent current estimates for the 1960-65 period (consistent with the estimates for 1960-64 computed in connection with the most recent current estimates. The 1960-65 estimates of net migration are, in effect, extrapolations of the 1960-64 period.) The difference between the initial projections of net migration for 1960-1965 for each State, and those developed consistent with the current estimates for 1960-64 were then used to modify the 1955-60 out-migration rates and the distribution of in-migrants. The adjustment was made with the following two conditions: (1) that the 1965 projected population derived as part of the initial projection procedure would be approximately the same as the population obtained by extrapolating the 1960-64 published population figures, and (2) that the migration rates would revert to their original levels (that is, of 1955-60) after 1970. In effect, the full adjustment was used for the 1960-65 period, and then reduced to one-half the amount for the 1965-70 period. For 1970-75 and later periods, no adjustment was made in the migration rates.

The amount of adjustment required to bring the 1965 projections in line with the current estimates was small relative to total population, but large, in many instances, relative to the size of the migration component. Of course, the amount of adjustment was greatest in those cases where net migration since 1960 differed substantially from that of the 1955-60 period. In only a few States, however, were the differences large enough to have an important impact on the projections. In many instances, however, because of these adjustments, the estimates of net migration for the short run do not conform with what is to be expected on the basis of the assumption of the "continuation of the 1955-60 gross migration rates."<sup>13</sup>

<sup>13</sup> One State in particular so affected was Nevada, where population gain due to net migration in the current decade is far surpassing that of the 1955-60 period. The impact on population is also important inasmuch as the net migration component represents a significant proportion of the total population. The approximate and tentative nature of the current estimate, the short-term period of the current estimate of net migration involved (basically 1960-1963), and the desire for uniformity in assumptions and in application of method, made inadvisable any special adjustment for Nevada which would have mitigated somewhat the effect of these diverse migration trends. Thus, by reverting to the 1955-60 migration rate after 1970, Nevada's projected rate of growth after 1970 is considerably slowed down compared with the period before 1970.

For the projections by age, however, no attempt was made to tie the projections directly to the most recent current State age estimates. Consequently, although the projections, by age, are generally consistent with current population estimates by broad age groups, there are a number of instances in which the 1970 projections are not in line with recently completed age estimates for 1964 and 1965 (planned for publication early in 1966). Discontinuities between the estimates and projections were noted particularly for the population 65 years and over in a few States. These situations come about mainly from differences in net migration of the aged population in the period since 1960 used in developing current estimates, as compared with the projected net migration based on the 1955-60 period. In such instances, the projected net change of the aged population over the short run implied in the projections as compared with estimated current levels should be interpreted accordingly.

#### OTHER SERIES

The projections described above result in four main series--that is, two assumptions concerning future interstate migration combined with two levels of fertility (labelled Series I-B, I-D, II-B, and II-D). Detailed tables 1 through 7 relate to these four series. A number of other series based on alternative interstate migration assumptions were developed to provide background data for selecting the projection series to be used for specific projects. These series are given in the appendix tables.

One alternative series, designated as Series III, assumes "no net migration" for each State during the projection period. In this series, it has been assumed that, regardless of gross population movement, net migration for each State in each period after 1965 will balance out to zero. This series is useful for measuring the impact on the population projections of alternative assumptions of future interstate migration. Separate projections under Series III are shown (a) including net immigration from abroad (300,000 per year as described earlier), and (b) assuming no net immigration from abroad after 1965. This latter series, in effect, represents the survivors of the population on each projection date of those now in the State (plus survivors of births).

Another alternative set of projections affects only the nonwhite population in States. Generally speaking, the rates and pattern of nonwhite migration differ to an appreciable degree from those of the white population. This alternative projection series has been derived to

illustrate the effect of interstate migration on the population distribution of the nonwhite population if interstate migration rates for whites and nonwhites should become equal. For this series, it was assumed that for each State, the nonwhite out-migration rates of the 1955-60 period will converge toward those of the white population, so that 50 years hence, the out-migration rates of the nonwhites, State by State, would be equal to those of the whites. It was further assumed that the distribution to State of destination would, in 50 years, also be the same as for the white population. The projection of the nonwhite population resulting from this procedure is given, in appendix table A-7, for 23 States with a nonwhite population in 1960 of 250,000 or more.

A special set of projections was also derived for the District of Columbia. The District of Columbia is a small area and exclusively urban. Its population composition, the city's position as the core of a large metropolitan area, and past suburbanization which has involved substantial interstate movement, all contribute to unusual gross interstate migration patterns. Furthermore, it is quite possible, because of present and planned land use, that the current population is not very far below the practical maximum. Consequently, migration assumptions I and II may not be at all appropriate for this area.

In recognition of these special circumstances, supplementary projections were derived for the District of Columbia, which result in substantially lower figures for 1985 than those derived by the uniform assumptions as shown in the detailed tables. The alternative projections for 1985 are 870,000 and 960,000. These alternative projections are based on somewhat different combinations of projections by color from those used in the main series. The projection of 870,000 (Series X) results from an assumption of no further net out-migration of white persons and the convergence of the 1955-60 gross migration rates for nonwhite persons toward those for whites for that period. This series, then, in effect, allows for considerable net out-migration of the nonwhites from the District of Columbia. The projection of 960,000 (Series Y) by 1985, on the other hand, assumes the continuation of the net out-migration of whites from the District, but at rates reduced somewhat from those of the recent past period, and for a somewhat slower convergence of the gross migration rates of nonwhites to those for the whites than that assumed for Series X. Projections by age, for the District of Columbia for 1975 and 1985 under these special assumptions are shown in appendix table A-8.

In contrast to these projections for the District of Columbia, recent local reports for the District suggest a population maximum of 810,000.<sup>14</sup>

Projections available from other sources.-- The projections given here are based on the specific methods and assumptions described above. Alternative methods and assumptions, also reasonable and logical in approach, could have been used which might have yielded substantially different results. In fact, there have been reports by other organizations which present population projections for all States. For example, two reports in which the methods differ substantially from those used here may be of particular interest to persons concerned with the impact on projections of alternative procedures. The two reports are:

"State Population, Net Migration, Labor Force and Industry Employment Trends to 1975," Regional Economic Projections Series - Report No. 65-1, prepared by the Center for Economic Projections, National Planning Association, Washington, D.C., March 1965.

Basic Economic Projections, United States Population, 1965-1980 by Pietro Balestra and N. Koteswara Rao, Stanford Research Institute, Menlo Park, California, 1964.

Population projections for individual States are also often available from State and local sources.<sup>15</sup> The derivations of some of these projections parallel, in some respects, the methodology described here; others are quite different

<sup>14</sup> The 1980 Population of Metropolitan Washington and Metropolitan Washington, Population Trends in the Sixties, prepared by Raymond F. Clapp, for the National Capital Planning Commission, National Capital Regional Planning Council, and the Government of the District of Columbia, October 1964 and March 1962, respectively.

in their approach, frequently attempting to assess the economic potential of particular areas, or perhaps reflect specific economic development plans.

#### RELATED REPORTS

The projections given here are consistent with the national population projections given in Current Population Reports, Series P-25, No. 286. They have been designed to be consistent with current estimates of State population for 1963 and 1964, published in Series P-25, No. 289. Revised estimates of State population for 1964 and provisional estimates for the States for 1965 (published in Report No. 324 of this series) have become available since these projections have been completed. Because of the timing involved, it was not possible to tie the State projections directly to the most recent State estimates. In most instances, however, the differences between the 1964 revised State estimates and the provisional ones are minor and have negligible impact on the projections. A comparison of the provisional 1964 estimates and the final revised 1964 State estimates is given in appendix table A-8.

National projections of school enrollment, educational attainment, and households and families, with which these projections would be generally consistent are planned for publication in Series P-25 reports. (Projections of educational attainment have recently been published in Series P-25, No. 305.) Projections of the labor force, by States, generally consistent with these State projections, are also planned for the near future by the Bureau of Labor Statistics.

<sup>15</sup> A bibliography of recently published State and local population projections is available from: Chief, Population Division, U.S. Bureau of the Census.
