Issued February 1975

## PROJECTIONS OF THE POPULATION OF THE UNITED STATES, BY AGE AND SEX, 1975 TO 2000, WITH EXTENSIONS OF TOTAL POPULATION TO 2025 (Advance report)

(The national population projections in this report supersede those presented in P-25, No. 493 and are consistent with national population estimates by age and sex for 1960-1974 presented in P-25, Nos. 519 and 529)

### INTRODUCTION

This advance report presents annual projections of the population of the United States by age and sex for the period 1975 to 2000, with projections of total population to 2025. The general approach, methodology, and assumptions are discussed here. The complete results and a detailed discussion of the results, methods, and assumptions will be published in a subsequent report in Series P-25. The detailed report will also include projections by race (white and black) for the period 1975 to 2000.

In addition to the use of an updated population base (July 1, 1974) and revised projections of mortality and net immigration, these projections differ from previous Census Bureau projections with respect to assumptions about future fertility. These changes are discussed in the following paragraphs.

This report includes projection series reflecting three different assumptions about the ultimate level of completed cohort fertility (average number of lifetime births per woman) instead of four assumptions as used in Census Bureau projections during the past two decades (table A). Because the present approach is not directly comparable with that used in past reports, the new projection series have been labeled numerically instead of alphabetically as was done in previous reports presenting national population projections.

Table A. ESTIMATES AND PROJECTIONS OF TOTAL POPULATION: 1970 TO 2025

(Numbers in thousands. As of July 1. Includes Armed Forces abroad. See text for methodology and assumptions)

Year	Series I	Series II	Series III

SOCIAL AND ECONOMIC STATISTICS ADMINISTRATION LIBRARY

The change to three fertility assumptions does not reflect the view that future population can now be determined more accurately than previously, but rather that the presentation of three series, along with guidelines for the selection of a series or a projected range, better serves the needs of users. (For further discussion, see the section on Selection of Projection Series.)

In the previous national projections report (P-25, No. 493), the ultimate completed cohort fertility assumptions were as follows: Series C-2.8, Series D-2.5, Series E-2.1, and Series F-1.8. In the current report, a one-child range and a series assuming ultimate completed cohort fertility at replacement level have been retained.<sup>1</sup> The fertility assumptions are as follows: Series I-2.7, Series II-2.1, and Series III-1.7. (These choices are discussed in the section on Principal Assumptions.)

While three projection series are presented in this advance report, the detailed report will also include two supplemental projection series that represent variants of Series II. The first is Series II-R which assumes that the completed cohort fertility rate will vary inversely with the relative size of a birth cohort before converging to replacement level in the long run. The possible influence of relative cohort size on social and economic factors which affect the level of fertility has recently received considerable attention from demographers.<sup>2</sup> This series will thus illustrate one alternative to the traditional assumption that completed cohort fertility will move smoothly toward an assumed ultimate level.

The second supplemental projection series assumes ultimate completed cohort fertility at replacement level and no net immigration. This series is labeled Series II-X and serves two main purposes. It illustrates

<sup>1</sup>Replacement level fertility is that required for a population to replace itself indefinitely, given projected mortality rates and in the absence of net immigration.

<sup>2</sup>Nathan Keyfitz, "Population Waves," in T. N. E. Greville, ed., *Population Dynamics* (New York: Academic Press), 1972, pp. 1-38. Richard A. Easterlin, "Relative economic Status and the American Fertility Swing," in Eleanor Bernert Sheldon, ed., *Family Economic Behavior* (Philadelphia: J. B. Lippincott), 1973, pp. 170-223. Ronald Lee, "The Formal Dynamics of Controlled Populations and the Echo, the Boom and the Bust," *Demography*, Vol. 11, No. 4 (November 1974), pp. 563-585.

one simple, albeit unrealistic, approach to a stationary population,<sup>3</sup> and taken in conjunction with Series II, which assumes net immigration from abroad, it illustrates the effect of the assumed net immigration on population growth.

The population projections in this report were prepared using the "inflation-deflation" variant of the standard "cohort-component" method. The inflation-deflation procedure, which reflects the pattern of estimated net census undercount by age and sex at the latest census, was not used in previous Census Bureau population projections; however, it was used in the preparation of the post-1970 census national population estimates by age and sex (reports P-25, Nos. 519 and 529) with which the projections in this report are consistent. (The inflation-deflation procedure is discussed further in the section on Methodology.)

## GENERAL METHODOLOGY

These projections were prepared using the inflation-deflation variant of the cohort-component method. In the cohort-component method, the components of population change (births, deaths, and net immigration) are projected separately for each birth cohort (persons born in each year). The initial (base date) population is carried forward year by year using projected survival rates and projected net immigration for each age-sex group. Annual births are projected for each future year and are carried forward in the same manner as the cohorts born before the base date.

The inflation-deflation procedure starts with the latest census population adjusted for estimated net census undercount by age and sex.<sup>4</sup> This "inflated" population is carried forward to the base date (with data on births, deaths, and net migration) and on to future years using the cohort-component method. For each future year the projected population is "deflated" to reflect the estimated pattern of net undercount by age and sex at the latest census.

The cohort-component method used alone preserves the actual pattern of population change by cohort. The inflation-deflation variant is generally preferable

<sup>3</sup>A stationary population has a constant size (zero growth) and a fixed age-sex distribution.

<sup>4</sup>For an analysis of the coverage of population in the 1970 census, see Bureau of the Census, *Census of Population and Housing: 1970, Evaluation and Research Program PHC(E)-4, "Estimates of Coverage of Population by Sex, Race, and Age: Demographic Analysis"* (Washington, D.C.: Government Printing Office), 1973.

because the vast majority of users of age data are interested in change over time in the population in specific ages or age groups and not in change over time in the population in cohorts.<sup>5</sup>

The population projections presented in this advance report are for all races combined. Projections were prepared separately by race (white, black, and other races) and were summed to obtain projections for the total population.

### PRINCIPAL ASSUMPTIONS

The principal assumptions about future fertility, mortality, and net immigration are discussed below. As noted earlier the projections were prepared by race; however, the figures shown here are for the total population. A full discussion of the assumptions will be included in the detailed report.

**Fertility.** Fertility is the component of population change that is subject to the greatest uncertainty in the future. Because of the difficulty of ascertaining the annual number of future births, even in the short run, alternative assumptions were made about the course of fertility. Together, these assumptions are believed to provide a reasonable range. No one series is likely to depict the future course of fertility for an extended period. Even if one of the alternative assumptions about cohort fertility turns out to be essentially correct, the trend in annual births could differ greatly from that projected because of changes in the tempo of childbearing.

The ultimate completed cohort fertility rate for Series II was set at 2.1 births per woman, which represents replacement level. Population growth obviously must cease at some point in the future; the difficult questions concern when this will occur, at what level, and the path by which zero growth will be reached.<sup>6</sup> (This does not preclude the possibility of

population decline after zero growth occurs.) While the average level of cohort fertility could differ somewhat from replacement level over an extended period of time, especially when combined with an assumption of substantial net immigration or net emigration, the long-term assumption of fertility at replacement level appears as reasonable as any other alternative.

In the shorter term Series II assumes that the average number of lifetime births will drop from about 3.2 for the birth cohorts of the early 1930's (who participated in the post-World War II "baby boom") to about 2.0 for the birth cohorts of the early 1950's (who are presently in the young childbearing ages) before converging to replacement level (table B). The cohort fertility assumption for the birth cohorts of the early 1950's reflects their fertility experience to date and their expectations regarding future births.<sup>7</sup>

The ultimate completed cohort fertility rates for Series I (2.7) and Series III (1.7) were set so as to have a one-child range (as was done in previous projection reports).<sup>8</sup> This appears to provide a reasonable range in projections of future births. The Series I assumption was set further above the Series II assumption than the Series III assumption was set below the Series II assumption. This choice reflects the idea that for average fertility to drop much below 2.0 births per woman, there would have to be a change in the social norm favoring at least two children per family and/or in the social and economic factors determining

<sup>5</sup>For a detailed discussion of the inflation-deflation procedure, see Bureau of the Census, Current Population Reports, Series P-25, No. 519, "Estimates of the Population of the United States, by Age, Sex, and Race: April 1, 1960 to July 1, 1973," issued April 1974, pp. 6-7.

<sup>6</sup>Ansley J. Coale, "Alternative Paths to a Stationary Population," and Norman B. Ryder, "A Demographic Optimum Projection for the United States," in U.S. Commission on Population Growth and the American Future, Demographic and Social Aspects of Population Growth, Charles F. Westoff and Robert Parke, Jr., eds., Vol. I of Commission research reports (Washington, D.C.: Government Printing Office), 1972, pp. 589-603 and 605-622, respectively.

<sup>7</sup>Bureau of the Census, Current Population Reports, Series P-20, No. 269, "Prospects for American Fertility: June 1974 (Advance data from the June 1974 Current Population Survey)," issued September 1974, p. 1. In 1974, wives 18-24 years old expected an average of 2.2 lifetime births. When adjusted to include those women who have not yet married or who will remain single, the birth expectations data suggest that the average lifetime fertility of all women 18-24 will be about 2.0. Birth expectations data are subject to error and to change, and the completed fertility of the birth cohorts of the early 1950's could be higher or lower than indicated.

<sup>8</sup>For a discussion of the fertility assumptions used in population projections for Canada (where the projected range of cohort fertility was set at 1.8 to 2.6), see Statistics Canada, Population Projections for Canada and the Provinces: 1972-2001, 1974, pp. 27-36.

Table B. COHORT FERTILITY ASSUMPTIONS FOR BIRTH COHORTS OF WOMEN: 1925 TO 2000

Birth cohort <sup>1</sup>	Exact age of cohort on Jan. 1, 1974 <sup>2</sup>	Cumulative cohort fertility up to Jan. 1, 1974	Completed cohort fertility rate <sup>3</sup>			Mean age of childbearing

- Represents zero. X Not applicable.

<sup>1</sup>A birth cohort is defined as those women born in the twelve-month period centered on January 1st of the year shown. For example, the 1925 cohort is comprised of females born July 1, 1924 to June 30, 1925.

<sup>2</sup>For example, on January 1, 1974, members of the 1925 birth cohort ranged in age from 48.5 to 49.5. On the average they were 49.0 years old.

<sup>3</sup>Average number of lifetime births per 1,000 women.

adherence to this norm.<sup>9</sup> For the birth cohorts of the early 1950's, the Series I and Series III completed cohort fertility assumptions were set so as to provide a range of about  $\pm 10$  percent around the Series II assumption.

One ultimate timing pattern of fertility with a mean age of childbearing of 26.0 (and a median age of childbearing of 25.6) was used for all series. (The selection of this timing pattern and the effect of the tempo of childbearing on future trends in annual births will be discussed in the detailed report.) The proportionate distribution of fertility by age of woman in the childbearing span (ages 14-49) was adapted from a set of model fertility schedules.<sup>10</sup>

<sup>9</sup>The historical aversion to childlessness and the one-child family are discussed in Judith Blake, "Can We Believe Recent Data on Birth Expectations in the United States?", *Demography*, Vol. 11, No. 1 (February 1974), pp. 25-44.

<sup>10</sup>Ansley J. Coale and T. James Trussell, "Model Fertility Schedules: Variations in the Age Structure of Childbearing in Human Populations," *Population Index*, Vol. 40, No. 2 (April 1974), pp. 185-258.

Calendar-year total fertility rates corresponding to the cohort fertility assumptions are shown in Table C. The total fertility rates were obtained by summing the appropriate birth rates by age of women for various cohorts for each calendar year. They were adjusted as necessary to fit smoothly with the low total fertility rate for 1973 and to provide a smooth trend from year to year.

**Mortality.** One set of projected survival rates was used for all series. These rates were adapted from mortality projections to the year 2000 by age and sex, which were prepared by the Office of the Actuary in the Social Security Administration and were based on an analysis of mortality by age, sex, and cause of death.<sup>11</sup> The projected survival rates used in preparing this report assume a small reduction in mortality until the year 2020 and no change thereafter. Average life

<sup>11</sup>Francisco Bayo and Steven F. McKay, *United States Population Projections for OASDHI Cost Estimates*, Actuarial Study No. 72, Office of the Actuary, Social Security Administration, July 1974.

expectancy at birth is assumed to increase from 67.9 for males and 75.7 for females in 1972 to 69.9 for males and 78.0 for females in 2020.<sup>1 2</sup>

The assumption of a modest reduction in mortality reflects trends during the past two decades. Mortality is sufficiently low from birth through the childbearing ages that any improvement in these ages would have a negligible effect on the future population in this age

**Table C. TOTAL FERTILITY RATES: 1970 TO 2015**

(Figures represent annual births expressed in terms of the implied completed fertility of 1,000 women)

2015 on.....	2,700	2,100	1,700

Note: These total fertility rates differ slightly from those published by the National Center for Health Statistics. These rates are the sum of single year of age central birth rates which are based on births adjusted for underregistration and population adjusted for estimated net census undercount.

<sup>1 2</sup>The figures for 1972 are slightly higher than those published by the National Center for Health Statistics (Monthly Vital Statistics Report, Summary Report - Final Mortality Statistics, 1972, Part I). The figures in this report were computed using an estimated population for 1972 based on the 1970 census population adjusted for estimated net undercount.

span. If a major medical breakthrough occurs in the control of major chronic diseases (cardiovascular diseases and cancer), then the future population in the older ages could be much larger than is projected here.

**Net Immigration.** All projection series (except for Series II-X) assume a net immigration of 400,000 per year with the distribution by age and sex based on recent patterns. This figure is close to the current annual level of alien immigration into the United States and to the average annual net civilian immigration into the United States during the past decade.<sup>1 3</sup> Because of the lack of reliable information, the net immigration assumption does not include an allowance either for aliens entering the United States illegally or for all the emigrants leaving the United States.

The level of net immigration to the United States is determined by legislation and by economic, social, and political conditions in the United States and abroad. These factors cannot be predicted with certainty. However, a substantial change in the future level of annual net immigration (e.g., an increase or decrease of 25 percent) would have a relatively small effect on future population, especially in comparison with the effect of a plausible range of future fertility.

#### LIMITATIONS

The population projections presented here are based on the general assumption that there will be no large-scale war, widespread epidemic, or other major catastrophe. While future levels of mortality and net immigration cannot be predicted exactly, changes in these two components are likely to have much less impact than changes in fertility on the size and composition of future population. As a result, projections of the population born before the July 1, 1974 base date are more reliable than projections of the population born subsequently. The larger the proportion of a projected population born after the base date, the more uncertain is the projection of that population.

<sup>1 3</sup>Immigration and Naturalization Service, 1973 Annual Report (Washington, D.C.: Government Printing Office), 1974, table 1. Bureau of the Census, Current Population Reports, Series P-25, No. 521, "Estimates of the Population of the United States and Components of Change: 1973 (With annual data from 1930)", issued May 1974, table 1. The fluctuations in annual net civilian immigration are due in part to fluctuations in the net movement of civilian citizens of the United States.

## SELECTION OF PROJECTION SERIES

The assumptions about the future course of the components of population change and the possibility of error in these assumptions have been discussed. The purpose of this section is to contrast projections, predictions, and forecasts of population and to provide some guidance for the selection of a projection series or a projected population range.<sup>14</sup>

Population projections are "correct" by definition (except for computational errors) because they indicate the population that would result if the underlying assumptions should turn out to be correct. Thus without an evaluation of the assumptions, there is no basis for choosing among alternative projections.

If the future population could be determined with negligible error, then only one projection series would be necessary, and it could be offered as a prediction. However as discussed earlier, this is not the case.

Population projections and population predictions thus represent the two ends of a scale. The area in between is represented by population forecasts. A population forecast may be thought of as a population projection accompanied by an indication of its accuracy. Ideally, this would be in the form of a statistical confidence interval, but this is not possible because the factors influencing population trends are neither perfectly understood nor perfectly predictable themselves. In practice, the indications of accuracy accompanying population projections represent individual (or collective) judgments which may differ greatly, even among presumed experts.

The attempt was made here to select reasonable assumptions about the future course of the components of population change and thus implicitly to "forecast" future population. However, the figures presented in this report are labeled conservatively as projections rather than forecasts to emphasize the difficulty of projecting population accurately (as

---

<sup>14</sup>For a more detailed discussion of this topic, see Nathan Keyfitz, "On Future Population," *Journal of the American Statistical Association*, Vol. 67, No. 338 (June 1972), pp. 347-363.

evidenced by projections of the United States' population made during the past few decades) and the importance of considering the purpose for which the figures are to be used.

Even if potential users agreed about the reasonableness of a set of population projections, they might select different projection series (or projected population ranges) to reflect the differing consequences of possible inaccuracy in varying situations.<sup>15</sup> For example, use of a population projection that turns out to be too high might incur costs for providing goods or services that are not needed whereas if the projection used turns out to be too low, the goods and services provided might not be sufficient to satisfy the demand. The user's assessment of these consequences determines whether he opts for a population series (or a projected population range) that appears "safe" on the high side, appears most accurate (meaning that the consequences of errors of equal magnitude on the high and low side are perceived to be equally undesirable), or appears "safe" on the low side.

## ROUNDING

Each figure in this report has been rounded independently to the nearest thousand from figures computed to the last digit; hence, the sum of parts may differ from the totals shown. Derived measures are based on the unrounded figures. Median ages are based on data for 5-year age groups.

## DETAILED TABLES

This report includes four detailed tables. Table 1 gives annual projections of the total population and the components of population change. Tables 2-4 show projections of the population by age and sex. In order to conserve space in this advance report, age detail for cohorts born before the July 1, 1974 base date is shown only once (in table 2) because these figures are the same for all three series. Age detail for cohorts born in whole or in part after July 1, 1974 is shown for each series and is delineated with heavy lines in tables 2-4 to facilitate the compilation of age detail for one projection series from two different tables.

---

<sup>15</sup>This concept is defined mathematically as the user's loss function. See Keyfitz, "On Future Population," p. 356.

**Table 1. ANNUAL PROJECTIONS OF THE TOTAL POPULATION AND COMPONENTS OF CHANGE FOR THE UNITED STATES: 1974 TO 2000**

**Table 3. SERIES I—PROJECTIONS OF THE POPULATION OF THE UNITED STATES  
BY AGE AND SEX: 1974 TO 1990, 1992, 1995, AND 2000**

(Numbers in thousands. As of July 1. Includes Armed Forces overseas. See text for methodology and assumptions. Figures inside heavy lines represent, in whole or in part, the survivors of projected births. Figures for ages not shown, which represent survivors of persons born before July 1, 1974, are the same as shown in table 2 for Series II)

**Table 4. SERIES III—PROJECTIONS OF THE POPULATION OF THE UNITED STATES BY AGE AND SEX: 1974 TO 1990, 1992, 1995, 2000—Continued**

(Numbers in thousands. As of July 1. Includes Armed Forces overseas. See text for methodology and assumptions. Figures inside heavy lines represent, in whole or in part, the survivors of projected births. Figures for ages not shown, which represent survivors of persons born before July 1, 1974, are the same as shown in table 2 for Series II)
