ACKNOWLEDGMENTS

This report was prepared under the general direction of John F. Long, Chief of the Population Projections Branch. Statistical assistance was provided by Thelma C. Hall and typing assistance was provided by Tammy R. Thomas. Computer programming was done by Jerome M. Glynn of the Computer Applications Staff. The graphs and figures were generated by Maureen P. Lynch of the Statistical Research Division. Publication review assistance was provided by Marion Gordon of Population Division. Overall direction was provided by Richard Engels, Assistant Division Chief, Population Division.

SUGGESTED CITATION

U.S. Bureau of the Census, Current Population Reports, Series P-25, No. 937, *Provisional Projections of the Population of States, by Age and Sex: 1980 to 2000*, U.S. Government Printing Office, Washington, D.C., 1983.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Postage stamps not acceptable; currency submitted at sender's risk. Remittances from foreign countries must be by international money order or by a draft on a U.S. bank. Current Population Reports are sold in two subscription packages: Series P-20, P-23, P-27, and P-60 are available for \$90 per year (\$22.50 additional for foreign mailing); Series P-25, P-26, and P-28 are available for \$22 per year (\$5.50 additional for foreign mailing). The single-copy price of this report is \$4.

Provisional Projections of the Population of States, by Age and Sex: 1980 to 2000

INTRODUCTION

This report presents projections of the resident population of each State by 5-year age groups and sex for July 1, 1990 and 2000. These projections represent the first series of State population projections released by the Census Bureau that are based on the 1980 census results and that are consistent with the middle series of national population projections published as Current Population Reports, Series P-25, No. 922. This set of projections is provisional in that it was developed with a cohort-component projections model employing residual measures of migration. The projections presented here are not forecasts of each State's future growth patterns. They present the results of continuing the migration patterns by age and sex estimated for the 1970-80 decade. When the full migration data are tabulated from the 1980 census question on residence 5 years ago, we will prepare a revised set of State population projections using more refined measures of migration.

These provisional projections use a standard cohort-component technique with separate assumptions about future levels of fertility, mortality, and net migration. Because of the lack of complete migration data, these projections use net migration rates rather than separate rates for immigrants and outmigrants. More specifically, the present set of projections assume that the rates of net migration by age and sex for each State estimated for the 1970-80 decade will continue unchanged for the next two decades. As a result of this approach, the States having net immigration in the 1970's automatically continue to receive large numbers of immigrants and register large population gains, while the remaining States continue to show slow or negative rates of population growth. Continuation of net migration rates is only realistic for short time periods. However, extending the 1970-80 net migration rates for the next two decades may provide usable results. Although we prepared only one series of population projections, this does not imply certainty about the course of future events. These projections indicate the levels of population that would result if the estimated rates of net migration by age and sex for 1970 to 1980 were to continue unchanged. These projections also incorporate the middle series mortality and fertility patterns developed for the latest set of national population projections which assume small decreases in mortality along with small increases in fertility.

RESULTS

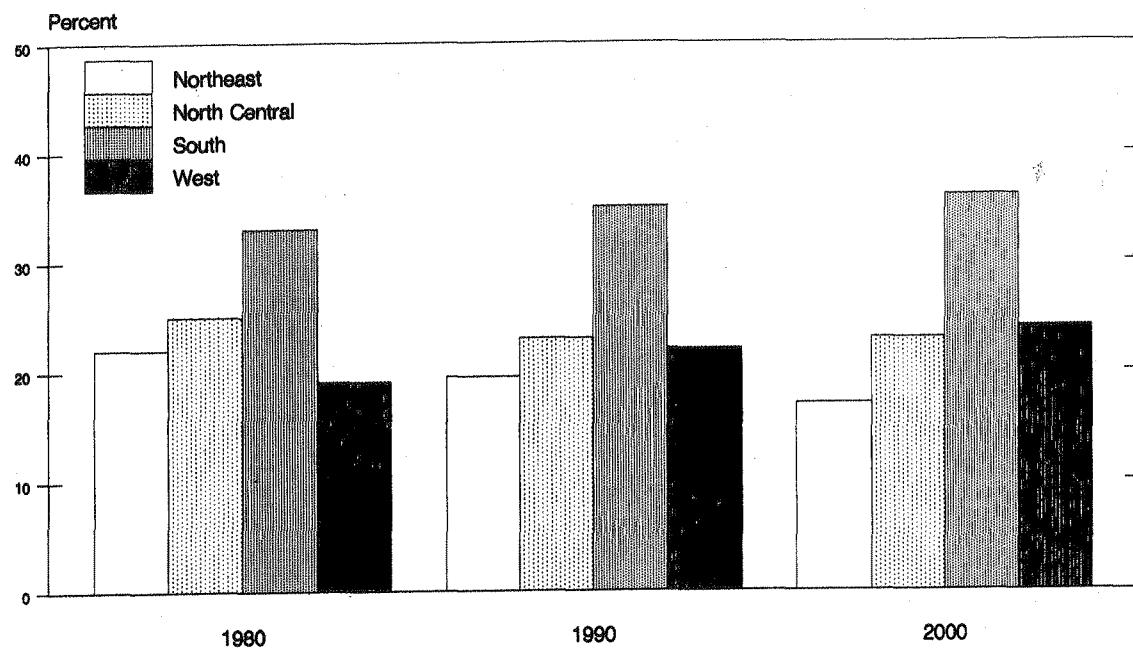

As these projections indicate, the patterns of growth exhibited during the decade of the 1970's continue through the remainder of the century (figures 1 and 2 and table 1). For the 1980-90 decade, the growth for the United States will increase to 9.7 percent, a rate above the 1970-80 growth of 9.0 percent. For the last decade of the century, the growth of the United States will drop to a little more than 7 percent. Regionally, the West will continue to be the fastest growing region in the country, growing 22.2 percent from 1980 to 1990, and 18.1 percent from 1990 to 2000.

Following the West, the South will maintain its pace as the second fastest growing region, increasing by 15.9 percent from 1980 to 1990, and 12.8 percent from 1990 to 2000. However, the South will add more people to its population than any other region, increasing its population size by almost 24 million between 1980 and 2000. The rate of growth in the North Central Region will slow to only 2 percent from 1980 to 1990, and then becomes negative for the 1990's. The Northeast will continue to lose population, declining 1.7 percent from 1980 to 1990, and over 4 percent from 1990 to 2000.

As indicated in figures 3 and 4, most of the rapidly growing States lie west of the Mississippi River. New Hampshire and Florida are the only States east of the Mississippi that will grow more than twice as fast as the rate of growth for the whole United States, while 10 states west of the Mississippi will grow that fast. Nevada is projected to be the most rapidly growing state, growing 59 percent between 1980 and 1990 and over 50 percent from 1990 to 2000. Nevada is followed by Wyoming, Arizona, and Utah, which also are located in the Mountain Region, as the fastest growing states in the Nation. While the mountain States will be the most rapidly growing States, Florida, California, and Texas will add more persons to their population between 1980 and 2000 than any other State, each adding over 6 million persons between now and the end of the century. From 1980 to 1990, Massachusetts, New York, Pennsylvania, Ohio, and the District of Columbia will be the only States that will lose population. For the 1990 to 2000 decade, Rhode Island, Connecticut, New Jersey, Illinois, Michigan, Iowa, and South Dakota will join this list and also register population losses.

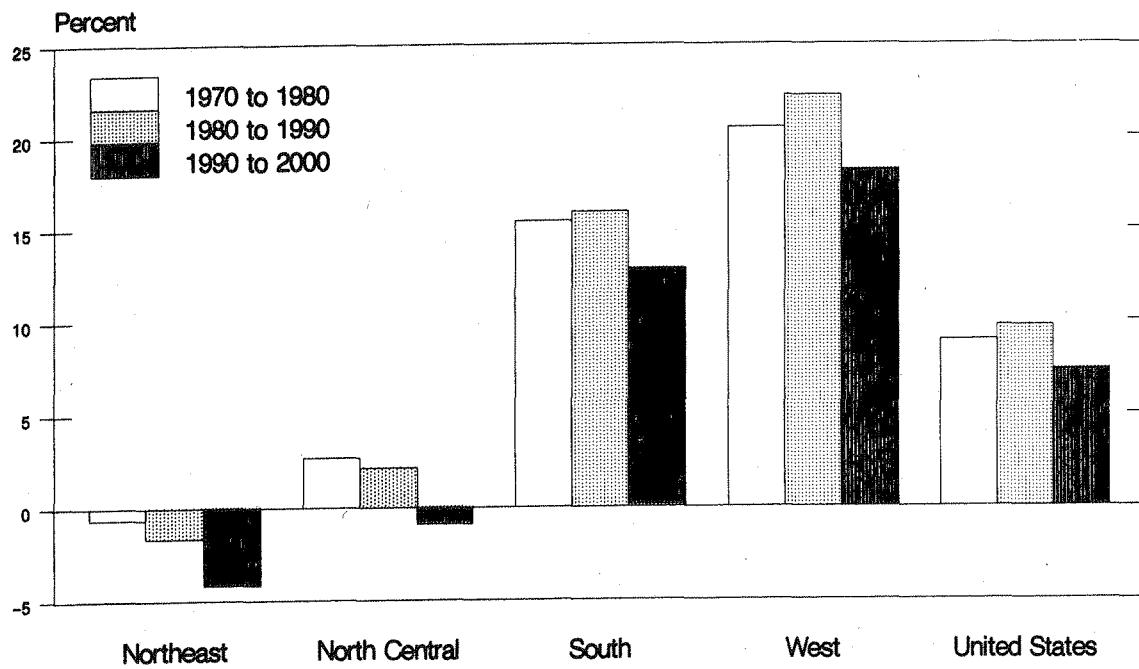

As a result of these uneven percentage growth rates, the West would increase its share of the Nation's population

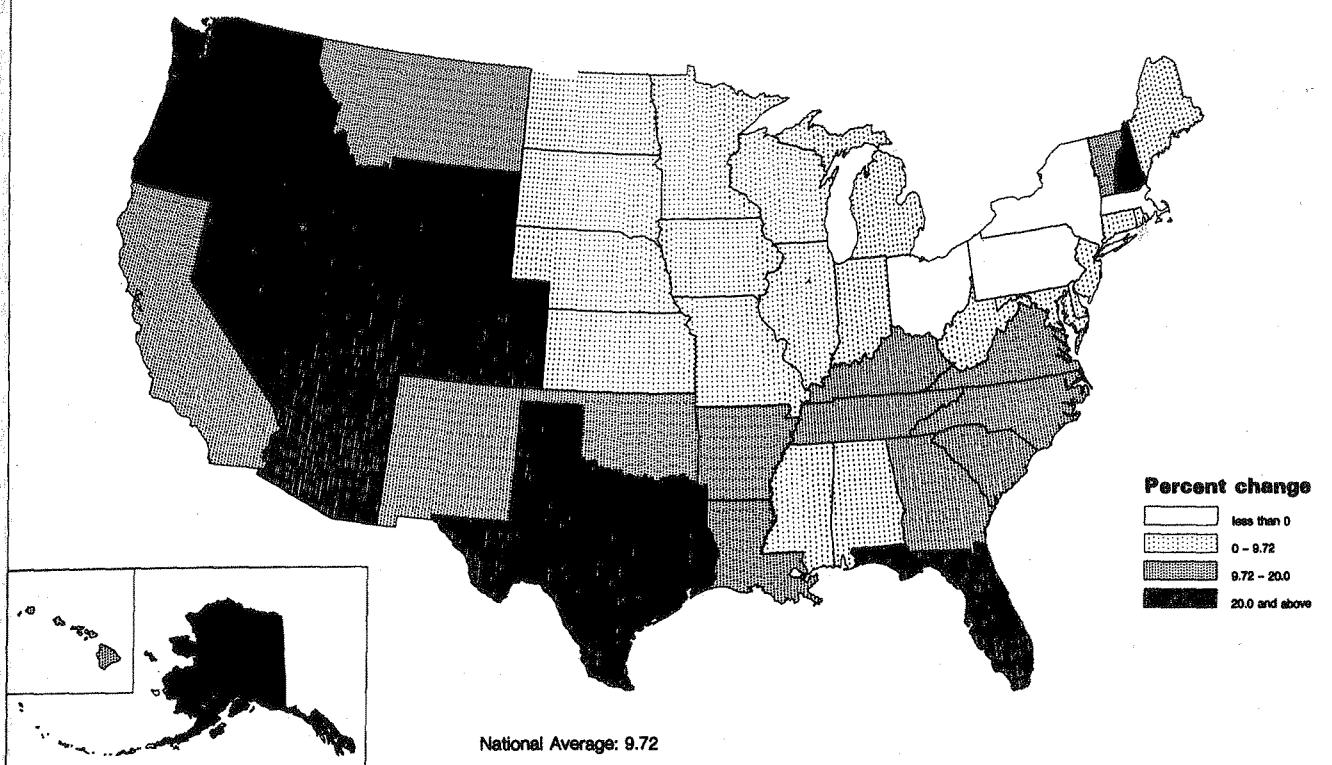

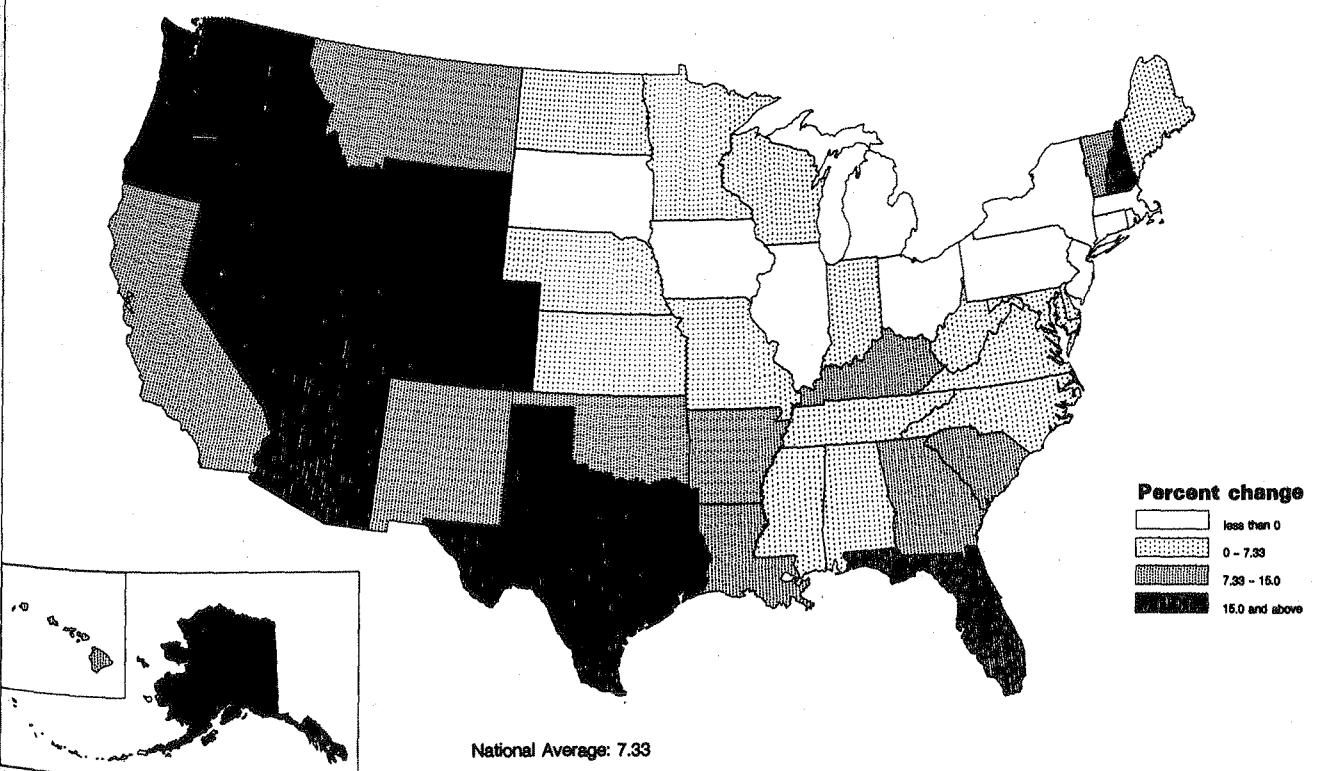

FIGURE 4:
Projected Percent Change in State Populations: 1990 to 2000

substantially, from 19 percent in 1980 to over 23 percent in 2000 (figure 2, table 1). The South would still house more persons than any other region in the country, increasing its percentage share from over 33 percent in 1980 to almost 37 percent in 2000. The share of the Nation's population in the Northeast and North Central Regions would decrease from a combined total of 48 percent in 1980 to 40 percent in 2000.

California will continue to be the largest State, housing over 11 percent of the U.S. population in the year 2000. However, if the present trends continue through 1990, Texas will surpass New York as the second largest State with over 7 percent of the U.S. population projected to reside there. By the year 2000, Florida will become the third largest State with New York moving to the fourth position with less than 6 percent of the U.S. population. By the year 2000, Alaska will no longer have the smallest population of the 50 States, having been replaced by Vermont with less than one-fourth of one percent of the U.S. population residing there.

As indicated in table A, the percentage of the total population aged 65 and over will continue to increase for the United States and each of the four regions. For the United States, the percentage aged 65 and over will increase from 11.3 percent in 1980 to 13.1 percent in 2000. The Northeast will continue to have the oldest age distribution with almost 15 percent of its population above the age of 64. In 2000, the West will have the youngest age distribution of the four regions, with over 22 percent of its population below age 15 and 45 percent between the ages of 15 and 44. Only 11 percent of the West's population will be above the age of 64 in 2000. The age distribution of the South and North Central Regions will mirror closely the age distribution of the entire United States. The South will have a greater proportion of elderly and lower proportions of persons aged 15 to 44. The North Central Region will have a higher proportion of its age distribution below the age of 15. As a consequence, the North Central and South Regions will have the highest dependency ratios (persons under 15 and over 64 divided by persons 15 through 64) in the year 2000.

METHODOLOGY

These projections were prepared using a cohort-component method whereby each component of population change—births, deaths, and net migration—are projected separately for each 5-year birth cohort. Basically, these projections begin with the April 1, 1980, census data for States by 5-year age group and sex. The data are carried forward to July 1, 1980, by adjusting the U.S. totals by age and sex to agree with the July 1, 1980, estimates of the resident population of the United States. Each State's population was projected to 1990 by applying a national set of survival rates by age and sex, and net migration rates by age and sex for the 1970-80 period for each State. Births for each State for the 10-year period were developed by applying national sets of fertility rates and State adjustment factors to the average number of females during the period. The births are then projected to 1990 in the same manner as the population

aged 10 and over. The final results are then adjusted to be consistent with the projections of the population of the United States by age and sex published in Current Population Reports, Series P-25, No. 922. A more complete discussion of each of the components follows.

Projections of Births

Since the population projections are by 5-year age groups, the number of births for each 5-year period was developed by applying national sets of age-specific birth rates and State adjustment factors to the average number of females during the period. The national sets of age-specific birth rates for 5-year age groups (appendix table A-1) from 10-14 years to 45-49 years for each 5-year period are consistent with the rates used in the middle series of the latest set of national population projections published as Current Population Reports, Series P-25, No. 922. These rates assume a small increase in the total fertility rate from a rate of 1.83 in 1980 to 1.96 in 2000. State adjustment factors, the ratio of the State total fertility rate in 1980 to the national rate (appendix table A-2), remain constant throughout the projection period.

The average number of females for each 5-year period is a linear interpolation by age of the female population at the beginning and ending points of each decade. Final State births by sex are obtained by applying the national sex ratio of 105 males per 100 females to the projected number of State births.

Projections of Deaths

Because regional life tables consistent with the 1980 census were not yet available, one set of age-sex specific mortality rates developed for the United States was used for all states in these projections. These projected rates, shown in appendix table A-3, are consistent with the middle series survival rates developed for and used in the national projections published in Current Population Reports, Series P-25, No. 922. They assume that life expectancy for males will increase from 70.7 in 1981 to 73.3 in 2005, and that life expectancy for females will increase from 78.3 in 1981 to 81.3 in 2005. For each decade, the beginning population in each State is survived forward by multiplying it by the national survival rates by age and sex.

Projections of Net Migration

At the State level, net migration has the greatest effect on population change. In general, it is also the component that shows the greatest degree of fluctuation and is the hardest to measure and project. Detailed migration data are generally available by tabulating responses to questions on place of previous residence. By combining the responses to previous and current residence, it is possible to measure the number of persons moving from one specific place to another (place-to-place migration). Such information can be used in projection models to link the potential number of immigrants to a State to the numbers of persons in each of the other States. Thus, the number of immigrants to a State can be based on historical patterns of place-to-place movement and the

number of persons in each of the other States. In addition, the use of place-to-place migration in a projection model also automatically insures that the sum total of all projected interstate migration is zero for the Nation.

In the absence of complete data on place-to-place migration, analysts have used the responses to the census questions to examine the total numbers of persons moving into and out of States (gross migration). Using these data in a projection model, it is possible to treat gross outmigration and inmigration separately. In this manner, outmigrants from a State are based on the rate of outmigration and the size and age structure of the State's population. As the population base of a State grows, it contributes more persons to a migrant pool. However, immigrants to a State are based on the appropriate share of all migrants who migrate into the State and is affected very little by the changing size of the State's population. Like the use of place-to-place migration, the use of gross migration also automatically insures that the sum total of all interstate migration is zero for the Nation. (See Current Population Reports, Series P-25, No. 796, for a more complete discussion of the advantages of gross migration data.)

In the absence of separate data on outmigration and inmigration, migration must be examined in terms of net amounts or rates. When direct observations of migration are not available, it is possible to estimate the amount or rate of net migration indirectly. However, while estimates of net migration may be the most readily available type of data, they are the least desirable for use in a projection model. In most cases, the estimated rates of net migration are multiplied by the base population of the State to determine the amount of net migration. Thus, States with net inmigration would continue to grow and in future decades automatically receive larger and larger numbers of immigrants. However, States with net outmigration are either growing very slowly or declining, thus contributing fewer and fewer numbers of outmigrants. Using this procedure, the sum total of all interstate migration eventually becomes unbalanced and requires greater and greater adjustments to balance it at zero.

Nonetheless, for purposes of this set of State population projections, it was necessary to compute the projections of migration using net migration rates. While it certainly would have been preferable to use more detailed migration data, place-to-place or gross-migration data by age and sex were not yet tabulated from the 1980 census. Rather than use the outdated data from the 1970 census or the partial data from the 1980 census, these projections use estimated rates of net migration by age and sex for the 1970-80 decade. While this method is unrealistic for longrun projections, it may provide usable data up until the year 2000.

Development of Residual Net Migration Rates: 1970-80

The traditional population equation

$$P_1 = P_0 + B - D + NM$$

where:

P_1 = population at the end of the period,

P_0 = population at beginning of the period,

B = births during the period,

D = deaths during the period,

NM = net migration during the period,

can be used to estimate the amount of net migration during the period. Provided that the other demographic data are available, net migration can be estimated according to

$$NM = P_1 - P_0 - B + D$$

This estimate of net migration is a residual estimate because it represents that part of population change not explained by births and deaths. As such, it is an indirect measure of migration and is affected by errors in the coverage of population and in the counts of births and deaths.

This residual technique can be employed to estimate the net migration for States between the 1970 and 1980 census dates. However, the difference in the coverage of the population between 1970 and 1980 is a severe problem that can distort the residual measurement of migration. As indicated in table B, a comparison of the 1980 census counts with the 1980 estimate of the United States based on the 1970 census reveals a difference of over 5 million persons. While this difference is partially attributable to less than adequate data on net immigration from abroad, a substantial part of this difference is probably due to an increase in the coverage of the population in 1980, compared with 1970. If estimates of residual net migration were developed for States using the 1970 and 1980 census counts, the sum total of the net migration for States would be 9,026,000 rather than 3,585,000.¹

Table B. Comparison of Population Estimate Based on 1970 Census With Actual Census Count: 1980

1970 census	203,302,000
Births, 1970-80.	33,499,000
Deaths, 1970-80	19,322,000
Net immigration, 1970-80.	3,585,000
1980 estimate based on 1970 census count	221,064,000
1980 census count.	226,505,000
Difference (count-estimate).	5,441,000

Each State's estimate of net migration would be biased upward and, when used in a projection model, would produce unrealistic results. Ideally, this problem could be overcome by adjusting both 1970 and 1980 census counts for the estimated patterns of undercoverage by age, race, and sex in each census. Unfortunately, final estimates of 1980 census coverage have not yet been completed, so this report employs an interim solution that corrects for the 1970 undercount but assumes complete coverage for 1980. An adjusted

¹ The net migration estimate represents the sum of interstate migration and net immigration from abroad. For the total U.S. population, the sum of interstate migration should balance at zero. Thus, the total net migration should equal net immigration from abroad, which measured 3,585,000 for the 1970-80 decade.

estimated of the State's population in 1970 was developed and utilized in the residual computation of net migration. The estimates of the corrected population for States in 1970, developed using demographic analysis, are consistent with the estimates published in Current Population Reports, Series P-23, No. 65.

However, this interim solution of adjusting only the 1970 population does not solve completely the "coverage" problem but does reduce the "error of closure" to 852,000—a difference that has to be handled by final pro rata adjustments of State populations to the national total. Thus, the sum total of net interstate migration and immigration from abroad (net migration) for 1970 to 1980, developed with the residual technique using the 1970 corrected populations, would be 4,437,000; a sum considerably closer to 3,585,000, the actual estimate of net immigrants from abroad. As table C shows, the differences between the 1980 estimates and 1980 census counts vary by age and sex. The census counted 1.4 million more females and 600,000 fewer males than were expected. Thus, in general, the residual net migration rates calculated for females should be higher than those calculated for males.

These projections employ the 1970-80 rates of net migration developed using the corrections to the 1970 census. The net migration rates utilized a combination of the forward and backward census survival and vital statistic techniques. For the census survival technique, deaths by age and sex were computed by applying a set of 10-year cohort death rates for the United States to the base population in each State. The numbers of deaths were then adjusted to the vital statistic estimate of deaths for the 10-year period. The differences between the 1980 census and the survivors of the 1970 corrected population yield the estimates of residual net migration shown in appendix table A-4.

Since the projections model utilized rates of civilian net migration, the base-date residual net migration had to be further refined to allow for changes in the military populations. The Department of Defense provided the 1970 and 1980 data for the military population in each State and the age and sex distribution of the total military population. (See appendix tables A-6 and A-7.) For these migration rates, we further assumed that the age and sex distribution of the total military population applied to all States. The differences between the resident net migration and the changes in the military population yielded the estimates of civilian net migration by age and sex for each State for 1970 to 1980. Dividing these numbers by the civilian survivors of the respective cohorts produced the rates of civilian net migration used in this projection scheme.

The Effects of Changing Census Coverage

Without the corrections for undercoverage in 1970, estimates of the total amount of net migration for 1970 to 1980 for each State would have been quite different (appendix table A-4). The 1970 census population is about 4.5 million lower than the population adjusted for undercount and increases the total amount of estimated net migration from 4.4 to 9.0 million persons. When the 1970 census populations form

the basis for the development of residual net migration, the amount of net inmigration increases or the amount of net outmigration decreases for all States except Wisconsin, Connecticut, and Utah. The largest differences occur in the South where the estimates of net undercount for 1970 were the greatest.

Appendix table A-4 also shows the preliminary estimates of net migration developed from the 1980 gross migration data. While the residual method of developing net migration would not be exactly comparable to the net difference of gross immigration and outmigration, a comparison of the 5- and 10-year net migration data is useful.

For most States, the 5- and 10-year estimates appear to be consistent. However, we plan a more complete analysis of consistencies and differences between these two data sets and related migration data, i.e., interstate migration flows computed from Internal Revenue Service returns, as part of the development of the next set of sub-national population projections.

To assess the effects of the different estimates of net migration, we prepared a projection of the total population of each State using the census-to-census estimates of net migration (appendix table A-5). Although for most States, the unadjusted estimates of net migration are higher than the adjusted series, the use of the unadjusted migration estimates in the projections scheme cannot increase every State's projection. The sum total of all States must still equal the United States projection. The unadjusted projections are higher for those States with the largest differences in the estimates of net migration. Again, the largest differences occur in the South, where in 1990, an additional 1.3 million persons would be added. The Northeast and North Central Regions would have 1.5 million fewer persons in 1990.

Adjustment to U.S. Controls

The preliminary projections of the population aged 10 and over by age and sex for each State added the projected numbers of net civilian migrants to the survived civilian population. For cohorts under age 5 and ages 5 to 9, the projected survived births for each 5-year period of the decade are added to the projected numbers of net migrants. Appendix table A-8 shows these projected components of population change for each State for the 1980 to 1990 and 1990 to 2000 periods.

While the rates of births and deaths were consistent with the middle series fertility and mortality rates developed for the recent set of national population projections, Series P-25, No. 922, the absolute numbers of events may not agree with the national controls.

Because of the errors in the computed sets of residual net migration and the inherent bias underlying the use of a constant set of net migration rates, the sum of the State projections were higher than the national projections. Pro rata adjustments to each State by age and sex brought the sum of the State projections into agreement with the middle series of United States projections. In most cases, these adjustment factors by age and sex for 1990 and 2000 are all less than 5 percent (appendix table A-9). However, in both 1990 and 2000, a downward adjustment of about 14 percent

Table C. Comparison of Population Estimates Based on 1970 Corrected Populations with Actual 1980 Census Counts, by Age and Sex

is required to bring the sum of males aged 30 to 34 into line with the United States totals. This is largely attributed to the artificially high net migration rates computed for males aged 30 to 34 in each State. Between 1970 and 1980, the size of the military population overseas changed from 1,099,000

to 515,000 — a decline of 584,000. This large return of Armed Forces from overseas increases the residual computation of net migration for States. However, for future years, the assumption of a constant level of Armed Forces overseas requires large adjustments to the males aged 30 to 34.

Tracking of State Population Projections

Comparison of previous set of State projections with 1980 census. Prior to the publication of these projections, the most recent set of State population projections prepared by the Bureau were in March 1979 in Current Population Reports, Series P-25, No. 796. Those projections used gross migration data from the 1970 census and postcensal estimates to 1975. The fertility and mortality assumptions were consistent with the series II set of national projections published as Current Population Reports, Series P-25, No. 704.

Three assumptions were developed about the future rates of net migration:

Series A. A continuation of the migration patterns by age, race and sex observed for the period 1965-75.

Series B. A continuation of the migration patterns by age, race and sex observed for the period 1970-75.

Series C. An illustrative series, based on the assumption of zero net domestic interstate migration between 1975 and 2000.

As appendix table A-10 indicates, the series B set of State population projections was generally closer to the 1980 decennial data than either the series A or C set of projections.

The largest differences between these projections and the 1980 census occurred in the Western States, where the series B set of State projections were 6.4 percent lower than the census data. For the Northeast, the turnarounds projected in the previous set of projections did not occur and the projected populations were 1.4 percent higher than the census data.

An evaluation of the previous set of projections is difficult because the differences between the projected and actual data can be due to biases in the basic projection model and to faulty assumptions. In the case of the previous set of projections, it is difficult if not impossible to parcel out the effects of the methodology and assumptions. In addition, a portion of the differences between the projections and the

decennial data are due to inconsistencies in coverage in the 1970 and 1980 censuses.

The choice of projection methodology for this and future sets of State population projections depends not so much on the past accuracy of each of the basic methodologies but rather on the availability of the necessary data, the appropriateness of each model's assumptions, and the required level of population detail.

In the present set of projections, the availability of net migration data only and the desired output of age data dictated the use of a net migration model. If reliable, timely, and valid place-to-place migration data can be developed, the Bureau of the Census will use a more disaggregated approach in future projections. Although, the use of the more disaggregated approach will not automatically increase the accuracy, it will provide the additional detail to analyze some of the reasons for future inaccuracies.

Comparison of present set of State projections with current estimates. Appendix table A-11 shows a comparison of the average annual percent changes derived from the estimated 1980 to 1982 data and the projected 1980 to 1990 data. The total growth for the U.S. is roughly comparable. However, the estimated trends by region are different from some of the projections. The projections continue to show population declines for the Northeast while the estimates indicate at least a shortrun reversal of the earlier trends. The Industrial States of the North Central Region show almost no population growth for the first part of the 1980's, while the projections did continue some modest population increases. The South, in particular Texas, does appear to be growing slightly faster than indicated by the projections, while the estimated and projected growth for the West are roughly comparable. However, while these comparisons between the projected and estimated rates of change do indicate the tentative nature of population projections, these comparisons are based on 2 years of growth and much change could occur between now and the year 2000.

Table 1. Projections of the Resident Population of Regions, Divisions, and States: 1980 to 2000

(Population rounded to hundreds. As of July 1, except as noted. Percent changes extend from July 1 to July 1 except as noted and are based on the population at the beginning of the interval. See text for discussion of methods and assumptions)

¹The census change represents the change from the April 1, 1970, census date to the April 1, 1980, census date.

²The percent change April 1, 1970, to April 1, 1980, represents the change from estimates of the corrected population April 1, 1970, to the April 1, 1980, census date.

Appendix

**Table A-1. Projections of Total Fertility Rates and Fertility Rates, by Age and Race:
Middle Fertility Series, 1980 to 2000**

(These rates represent the average annual number of births per 1,000 females for the 5-year interval)

Age and race	Total fertility rate	10 to 14 years	15 to 19 years	20 to 24 years	25 to 29 years	30 to 34 years	35 to 39 years	40 to 44 years	45 to 49 years	General fertility rates ¹
All races:										
1980-1985.....	1,858.8	1.4	53.2	115.0	114.4	62.3	21.2	4.1	0.2	68.2
1985-1990.....	1,927.5	1.3	54.1	114.5	119.0	70.8	21.7	4.0	0.2	67.4
1990-1995.....	1,951.5	1.1	50.7	117.6	117.6	75.7	23.4	3.9	0.2	64.5
1995-2000.....	1,940.8	1.1	51.1	113.6	120.9	73.2	24.1	3.9	0.2	61.4
White:										
1980-1985.....	1,783.2	0.8	45.2	109.7	114.7	61.8	20.4	3.8	0.2	65.2
1985-1990.....	1,856.1	0.8	46.2	109.5	119.4	70.5	20.9	3.7	0.2	64.7
1990-1995.....	1,885.0	0.7	43.8	112.9	118.0	75.3	22.6	3.6	0.2	62.1
1995-2000.....	1,877.6	0.7	44.4	109.3	121.3	72.7	23.3	3.6	0.1	59.0
Black:										
1980-1985.....	2,321.8	4.4	99.9	147.6	112.8	65.8	27.1	6.4	0.3	88.6
1985-1990.....	2,352.8	3.9	98.5	143.6	117.0	73.5	27.7	6.2	0.3	85.1
1990-1995.....	2,337.4	3.2	89.3	144.9	116.0	78.7	29.2	5.9	0.3	79.7
1995-2000.....	2,287.6	3.1	86.2	137.4	119.1	75.9	29.7	5.7	0.3	74.8

¹The general fertility rate represents the average annual number of births per 1,000 females aged 15 to 44 for the 5-year interval.

Note: These projected fertility rates are consistent with the middle fertility assumption used in Current Population Reports, Series P-25, No. 922.

Table A-2. Estimates of State Differentials in Fertility

(These ratios represent the ratio of the State total fertility rate to the national rate in 1980)

¹Represents net migration as a percent of the 4/1/70 population + births during the decade - deaths during the decade.

²Includes immigration from abroad for the 1975 to 1980 period.

Table A-5. Effects of Correcting for Census Coverage Differentials on Population Projections: 1990 and 2000

(Numbers rounded to hundreds. As of July 1. Corrected series represents projections using net migration based on 1970 corrected population. Uncorrected series represents projections using net migration based on 1970 census populations. See text for discussion of methods and assumptions)

Table A-11. Comparison of Estimated and Projected Average Annual Percent Change for the 1980 Decade, for Regions, Divisions, and States

(Estimated change represents the average for the period 4/80 to 7/82. Projected change represents the average for the period 4/80 to 7/90)

Region, division, and State	Postcensal estimates		Projections		Region, division, and State	Postcensal estimates		Projections	
	Population July 1, 1982	Average annual percent change	Projection July 1, 1990	Average annual percent change		Population July 1, 1982	Average annual percent change	Projection July 1, 1990	Average annual percent change
