# ANNUAL 1987 ABSORPTIONS (Completions in 1986) 

## SUMMARY

During 1986, completions of privately financed, nonsubsidized, unfurnished rental apartments in buildings of five units or more totaled 407,600 units. This represents an increase of about $12( \pm 7)$ percent from the 364,500 units completed in 1985. Sixty-six percent of these units were rented (absorbed) within the first 3 months of completion, 84 percent within 6 months, 92 percent within 9 months and 96 percent were rented within a year of completion.

About 51 percent of new unfurnished apartments were built with two bedrooms and 42 percent were built with one bedroom. Units with 3 or more bedrooms and those with no bedrooms accounted for 3 and 4 percent, respectively. The median asking rent for apartments completed in 1986 was $\$ 457$, an increase of about $6( \pm 3)$ percent from the $\$ 432$ median for similar units completed in 1985 . Units renting for $\$ 500$ or more accounted for 37 percent of newly completed units in 1986, an increase of about $9( \pm 3)$ percentage points from the 28 percent in 1985 .

About 42 percent of new unfurnished apartments were built in the South, down $4( \pm 3)$ percentage points from the 46 percent built in that region in 1985, and
down $20( \pm 3)$ percentage points from the 62 percent built in 1984. Approximately 38 percent were built in the West, 16 percent in the Midwest, and only 4 percent in the Northeast. Asking rents were highest in the Northeast with a median asking rent of $\$ 500$ or more.

Most (95 percent) of the unfurnished apartments built in 1986 are inside metropolitan statistical areas and are evenly divided between central cities ( 46 percent) and suburban areas (49 percent).

The statistics in this report are based on a sample survey and consequently they are subject to sampling variability. ${ }^{1}$ Estimates derived from different samples would differ from one another. The standard error of a survey estimate is a measure of the variation among the estimates from all possible samples. Estimates of standard errors can be calculated by using tables A and B. They allow us to construct interval estimates with prescribed confidence that the interval includes the average of the estimates from all possible samples. For all the change statements made in this report, 90 -percent confidence intervals for statistical comparisons can be constructed by using the 90 percent deviate shown in

[^0]Table 1. Absorption Rates for Unfurnished Apartments Completed, by Geographic Area:1986
(Privately financed, nonsubsidized, unfurnished, rental apartments in buildings with five units or more. Data may not add to total due to rounding).

| Geographic areas | Total |  | Percent absorbed within- |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Number | Percent | 3 months | 6 months | 9 months | 12 months |
| United States, total. . . . . . . | 407,600 | 100 | 66 | 84 | 92 | 96 |
| Inside MSA's | 385,700 | 95 | 66 | 84 | 92. | 95 |
| In central city. | 187,900 | 46 | 64 | 82 | 91 | 95 |
| Not in central city | 197,800 | 49 | 67 | 85 | 93 | 96 |
| Outside MSA's | 21,900 | 5 | 68 | 88 | 92 | 96 |
| Northeast | 16,900 | 4 | 70 | 85 | 92 | 95 |

| South. | 171,700 | 42 | 62 | 81 | 91 | 95 |
| West. | 154,500 | 38 | 67 | 86 | 93 | 96 |

[^1]parentheses after the change; however, when a 90 percent confidence interval contains zero, we are uncertain whether or not the change has occurred. In addition, some of the statistical findings which are not patt of the tables are also provided with a 90 percent deviate.
in 1986, a total of about 550,200 apartments were completed in buildings with five units or more which was not significantly different from the 533,300 apartments completed in 1985. Seventy-four percent were nonsubsidized, unfurnished, rental apartments; this is $6( \pm 3)$ percentage points higher than the 68 percent in 1985 . Of the remainder, cooperatives and condominiums (101,700 units) accounted for 18 percent of the new completions, down $7( \pm 2)$ percentage points from 25 percent in 1985.

About two-thirds ( 66 percent) of all cooperative and condominium apartments built in 1986 were two-bedroom units. Forty-two percent of all newly-constructed cooperatives and condominiums were built in the South, 28 percent in the Northeast, 23 percent in the West, and only 8 percent in the Midwest. The number of cooperatives and condominiums built in the Midwest and West remained about the same in 1986 as in 1985 while the number built in the Northeast increased by 50 ( $\pm 21$ ) percent from 18,900 in 1985 to 28,400 in 1986, and the number built in the South decreased $47( \pm 8)$ percent from 80,400 to 42,700 . The 3 -month absorption rate for cooperative and condominium apartments in 1986 was 74 percent. The 3 -month absorption rate for cooperatives and condominiums completed in the Northeast was 91 percent, compared with the 3 -month rates in the upper 60's for the other three regions. The median asking price for condominium apartments built in 1986 was $\$ 94,600$.

Furnished rental units accounted for 2 percent of the total number of privately financed apartments in buildings with five units or more. Furnished units tended to be smaller than unfurnished units. Apartments with two bedrooms accounted for 51 percent of unfurnished units while less than one-fifth (19 percent) of the furnished had two bedrooms. Only about 4 percent of all unfurnished apartments had no bedroom while 30 percent of the furnished units were no-bedroom apartments.

Federally subsidized properties accounted for 4 percent of total units completed. While completions of this type of units decreased from 28,500 in 1984 to 12,000 in 1985, they increased in 1986 to 23,300 . Despite this increase, completions of federally subsidized units remain at historically low levels. These units are built under the following programs of the Department of Housing and Urban Development: Low Income Housing Assistance (Section 8), Senior Citizens Housing Direct Loans (Section 202), and all units in buildings containing apartments in the FHA rent supplement program. An additional 1 percent of all newly constructed units include timesharing units, continuing care retirement units, and turnkey housing (privately built for and sold to local public housing authorities subsequent to completion). The data
on privately financed units include privately owned housing subsidized by State and local governments.

## SAMPLE DESIGN

The Survey of Market Absorption (SOMA) is designed to provide data concerning the rate at which nonsubsidized and unfurnished privately financed units in buildings with five or more units are rented (or absorbed), In addition, data on characteristics of the units, such as remt and number of bedrooms, are collected.

The buildings selected for SOMA are those included in the Census Bureau's Survey of Construction (SOC)². For SOC, the United States is first divided into primary sampling units (PSU's) which are sampled on the basis of population. Next, a sample of permit-issuing places is selected within each sample PSU. Finally, all buildings with five or more units within sampled places as well as a subsample of buildings with one to four units are selected.

Each quarter, a sample of buildings with five or more housing units in the SOC sample reported as completed during that quarter come into sample for SOMA. Buildings completed in nonpermit-issuing areas are excluded from consideration. Information on the proportion of units absorbed $3,6,9$, and 12 months after completion is obtained for units in buildings selected in a given quarter in each of the next four quarters.

## ESTIMATION

Unbiased quarterly estimates are formed by multiplying the counts for each building by its base weight (the inverse of its probability of selection) and then summing over all buildings. The final estimate is then obtained by multiplying the unbiased estimate by the following ratio estimate factor:
total units in $5+$ buildings in permit-issuing areas as estimated by the SOC for that quarter
total units in $5+$ buildings as estimated by SOMA for that quarter

This procedure produces estimates of the units completed in a given quarter which are consistent with the published figures from the Housing Completions Series, ${ }^{3}$ and also reduces, to some extent, the sampling variability of the estimates of totals. Annual estimates of completions are obtained by summing the four quarterly estimates.

[^2]It is assumed that the absorption rates and other characteristics of units not included in the interviewed group or not accounted for are identical to rates for units where data were obtained. The noninterviewed and not-accounted-for cases constitute less that 2 percent of the sample housing units in this survey.

## RELIABILITY OF THE ESTIMATES

There are two types of possible errors associated with data from sample surveys: sampling and nonsampling errors. The following is a description of the sampling and nonsampling errors associated with SOMA.

## Nonsampling Errors

In general, nonsampling errors can be attributed to many sources: inability to obtain information about all cases in the sample; definitional difficulties; differences in interpretation of questions; inability or unwillingness of respondents to provide correct information; and errors made in processing the data. These nonsampling errors also occur in complete censuses. Although no direct measurements of the biases have been obtained, it is believed that most of the important response and operational errors were detected in the course of reviewing the data for reasonableness and consistency.

## Sampling Errors

The particular sample used for this survey is one of a large number of possible samples of the same size that could have been selected using the same sample design. Even if the same questionnaires, instructions, and interviewers were used, estimates from each of the different samples would differ from each other. The deviation of a sample estimate from the average of all possible samples is defined as the sampling error. The standard error of a survey estimate attempts to provide a measure of this variation among the estimates from the possible samples and, thus, is a measure of the precision with which an estimate from a sample approximates the average result of all possible samples.

As calculated for this survey, the standard error also partially measures the variation in the estimates due to response and interviewer errors (nonsampling errors), but it does not measure, as such, any systematic biases in the data. Therefore, the accuracy of the estimates depends on both the sampling and nonsampling error measured by the standard error, biases, and some additional nonsampling errors not measured by the standard error. The sample estimate and its estimated standard error enable the user to construct confidence intervals, ranges that would include the average result of all possible samples with a known probability. For example, if
all possible samples were selected, each of these were surveyed under essentially the same general conditions, and an estimate and its estimated standard error were calculated from each sample, then:

1. Approximately 68 percent of the intervals from one standard error below the estimate to one standard error above the estimate (i.e., 68 -percent comfidence interval) would include the average result of all possible samples.
2. Approximately 90 percent of the intervals from 1.6 standard errors below the estimate to 1.6 standard errors above the estimate (i.e., 90 -percent confidence interval) would include the average result of all possible samples.
3. Approximately 95 percent of the intervals from two standard errors below the estimate to two standard errors above the estimate (i.e., 95-percent confidence interval) would include the average result of all possible samples.

For very small estimates, the lower limit of the confidence level may be negative. In this case, a better approximation to the true interval estimate can be achieved by restricting the interval estimate to positive values, that is, by changing the lower limit of the interval estimate to zero.

The average result of all possible samples either is or is not contained in any particular computed interval. However, for a particular sample, one can say with specified confidence that the average result of all possible samples is included in the constructed interval.

The conclusions stated in this report are considered significant at the 90 -percent confidence level.

The reliability of an estimated absorption rate (i.e., a percentage) computed by using sample data for both the numerator and denominator depends upon both the size of the rate and the size of the total on which the rate is based. Estimated rates of this kind are relatively more reliable than the corresponding estimates of the numerators of the rates, particularly if the rates are 50 percent or more.

The figures presented in tables $A$ and $B$ are approximations to the standard errors of various estimates shown in the report. Table A presents standard errors for estimated totals, and table B presents standard errors of estimated percents. in order to derive standard errors that would be applicable to a wide variety of items and could be prepared at a moderate cost, a number of approximations were required. As a result, the tables of standard errors provide an indication of the order of magnitude of the standard errors rather than the precise standard error for any specific item. Standard errors for values not shown in tables $A$ or $B$ can be obtained by linear interpolation.

## HLUSTRATVE USE OF STANDAPD ERROR TABLES

Table 1 of this repon shows that 34,400 units completed in 1986 rented for $\$ 300$ to $\$ 349$. Table $A$ shows the standard error of an estimate of this size to be approximately 3,200 . To obtain a 90 -percent confidence interval, multiply 3,200 by 1.6 and add and subtract the result from 34,400 yielding limits of 29,300 and 39,500 . The average estimate of units completed in 1986 renting for $\$ 300$ to $\$ 349$ may or may not be included in this
computed interval, but one can say that the average is incfuded in the constructed interval with a specified confidence of 90 percent.

Table 1 also shows that the rate of absorption after 3 months for these units is 71 percent. Table $B$ shows the standard error on a 71 percent rate on a base of 34,400 to be approximately 4.2 percent. Multiply 4.2 by 1.6 (yielding 6.7) and add and subtract the result from 71. The 90 -percent confidence interval for the absorption rate of 71 percent is from 64.3 to 77.7 .
