Acknowledgments

This report was prepared under the general direction of **John F. Long**, Chief of the Population Projections Branch. **Joan B. Taylor** and **Thelma C. Hall** provided statistical assistance, and **Sharon S. Goldsmith** provided typing assistance. **Rosalyn M. Green**, **Marie Pees**, and **Norman Kaplan** provided computer programming and assistance. Overall direction was provided by **Jeffrey S. Passel**, Assistant Division Chief, Population Division.

Gregory K. Spencer; **Andrei Rogers**, University of Colorado; **Frans Willekens**, Netherlands Interuniversity Demographic Institute; and Members of the Federal State Cooperative Program for Population Projections provided professional consultation on the methodological development.

The staff of Publications Services Division, **Walter C. Odom**, Chief, provided publication planning, design, composition, editorial review, and printing planning and procurement.

Projections of the Population of States, by Age, Sex, and Race: 1988 to 2010

INTRODUCTION

This report presents projections of the resident population for the 50 States and the District of Columbia by age, sex, and race for 1988 through 2010. These projections represent the first set of Census Bureau State population projections produced by single years of age for individual calendar years. They were produced using an enhanced methodology that solves several technical problems of the previous set of State population projections and permits updating for recent migration trends.¹

The projections presented here differ from forecasts in that they only present the results of the mathematical projection model *given* explicitly stated assumptions. These assumptions usually emphasize recent trends present in the data, not anticipated or desired trends. The advantage of this approach is that the projections form a baseline showing the implicit direction of current trends. The resulting projections represent a consistent set for all States that were developed using a consistent methodology and a consistent set of assumptions and that add to the projected national resident population. With this type of approach, the projections of one State can easily be compared to the projections of another State. Small and often unforeseeable changes in economic, social, or demographic conditions in any State can and will cause future population change to deviate from the projected trends.

Although we include only one set of projections developed by the Bureau in this report, this does not imply certainty about the future course of events. These projections were the first to utilize an enhanced methodology and newly created data sets. Much of the developmental work involved gathering, analyzing, and evaluating these historical data sets. As such we were able to develop only one set of assumptions about each of the components of population change. However, in the next set of State population projections to be developed by the Bureau, multiple assumptions will be developed and alternative sets of projections will be presented.

The present set of State population projections utilizes a mathematical projection model known as the cohort-component method.² This method permits separate assumptions to be made for each of the components of population change: births, deaths, internal migration, and international migration. These projections are the first to incorporate annual State-to-State flows of migrants developed from annual administrative data; these data have been used in producing current population estimates for States for several years.³ These data are used in combination with decennial census migration data as a basis for projecting future migration. The use of migration data from administrative records permits the development of annual population projections incorporating the most recent migration trends.

The projections are consistent with July 1, 1986, population estimates for States. The assumptions concerning future levels of fertility, mortality, and net immigration are consistent with the middle series of the national population projections to be published in Current Population Reports, Series, P-25, No. 1018. Internal migration assumptions in these State projections are based on the annual State-to-State migration data for the 1975-86 period. Although certain parts of the historical period examined (1975 through 1986) may represent unique circumstances in many of the States, the past does in general provide a basis for projecting the future.

STATE PRODUCED PROJECTIONS

If one's interest is in projections for a single State rather than a consistent set of projections for all States, it can be useful to examine population projections prepared by State agencies. Most States have at least one public agency that prepares population projections at that level; most of these agencies are members of the Federal State Cooperative Program for Population Projections. These projections represent an alternative to the projections developed by the Bureau. Because each State is not required to produce a set of projections

²Shryock, Henry S., and Jacob S. Siegel, et al., *The Methods and Materials of Demography*, Vol. 2, U.S. Government Printing Office, Washington, D.C., 1971, p. 377.

³See Current Population Reports, Series P-25, No. 957 for a complete discussion of the development of migration data from the matched tax returns.

¹Current Population Reports, Series P-25, No. 937.

consistent with other States, the individual State projections can be based on an assortment of models that incorporate a wider range of variables and data.

Table 8 in this report presents the State population projections that were prepared by each of the participating agencies listed in appendix B. Each of these projections was prepared using the State's own methodological approach and set of assumptions. Therefore, the results presented for one State may not be comparable to the projections presented for another State. Before using or evaluating the projections shown in this particular table, we suggest that users contact the individual State agencies to obtain a more complete discussion of their methods and assumptions.

PROJECTED POPULATION TRENDS

The projections of State population by age, sex, and race shown in tables A through K and 1 through 7 of this report result from the methodology and detailed assumptions about each of the components of population change presented in the methodological section of this report.

Population Size and Growth

Regional growth. Under the assumptions in these projections, the South and the West would continue to be the fastest growing regions in the United States. Between 1986 and 1990, the West is projected to grow by 7.2 percent, almost twice as fast as the United States (table A). The West is expected to add about 3.5 million persons to its population during this period, with just over half of this growth from natural increase (table B). Between 1986 and 1990, almost one-half of all growth in the U.S. population is projected to occur in the South. During this period, the South is projected to grow by 5.2 percent; this growth is nearly evenly distributed between natural increase and net migration. In contrast, between 1986 and 1990, the Northeast is expected to grow by only 1.1 percent and the Midwest by 0.8 percent. The projected growth in these regions would result from the excess of births over deaths that offsets net outmigration to other regions.

By 1990, the West would no longer be the smallest region, moving ahead of the Northeast. The South would continue to be the most populous region with almost 35 percent of the U.S. population residing there. By 1995, the Midwest would reach its peak size under these assumptions and is projected to decline slowly after 1995.

During the 1990's, the regional differentials in population growth projected during the 1986-90 period remain similar (table A). As the population of the United States continues to age, the levels of natural increase are projected to decline. Under the assumptions used in these projections, during the 1990's, most of the increase in the U.S. population would continue to be concentrated in the South and West (table C). The West would continue to be the fastest growing region, increasing 13.7 percent. Its younger population and higher fertility rates would mean that natural increase would account for just over one-half of the growth. The South would continue to follow the West as the second fastest growing region. For the decade of the 1990's, over one-half of the South's total growth would be from migration. During the 1990's, the Midwest is projected to experience a population decline as the excess of births over deaths may not be sufficient to compensate for the net outmigration to other regions of the United States. While the Northeast is projected to experience the lowest levels of natural increase, its large net immigration from abroad would probably be sufficient to create small population increases.

The patterns of regional growth shown for the last 14 years of this century are projected to continue into the next century (table D). As the U.S. population continues to age, the levels of natural increase would continue to decline. Almost all of the growth in the United States would continue to be concentrated in the South and West Regions under the assumptions of the projections. Over one-half of the South's projected growth would continue to be from net immigration, while a majority of the West's projected growth would be from natural increase. By 2010, the South would still be the most populous region increasing its share of the total population to over 37 percent, while the West is projected to

Table A. Estimates and Projections of the Population of Regions: 1986-2010

(Numbers in thousands. As of July 1. Percent change is based on total beginning population)

Region	1986 estimate	Projections			Percent of total population				Percent change

¹These components do not include the adjustment to bring the sum of the State projections by age, sex and race into agreement with the national population projections. Thus the net sum of the components will not equal the net change in population.

²The internal migration component for regions includes the net movement of persons to the Armed Forces overseas. For the United States total, this component reflects only the net sum of internal migration which is zero.

Source: Derived from table 4.

year 2000. This ranking of the top five States would then remain constant from 2000 through 2010. Between 1986 and 2000, the list of the 10 most populous States would only be altered by Georgia, which would replace North Carolina.

In 1990, Wyoming is projected to head the list of the least populous States, followed by Vermont, as Alaska is projected to move into third place. In 2000, Wyoming and Vermont would remain the smallest and next smallest States, respectively, but North Dakota would lose population and become the third smallest State, pushing Alaska to the fourth position.

Between 1986 and 1990, nine States are projected to have a growth rate more than twice that of the Nation (table F and figure 1). Eight of these nine States (Arizona, Nevada, New Mexico, Florida, Georgia, Alaska, California, and Hawaii) are located in the South or West (figure 1), with New Hampshire as the exception. Arizona is projected to be the fastest growing State, increasing its population by 13.1 percent during the 4-year period.

During the 1990's, these nine States plus Texas are projected to grow at a rate twice that for the United States (table F and figure 2). During the last decade of this century, Arizona is again projected to be the fastest growing State, increasing its population by 23.1 percent. Florida would continue to be one of the fastest growing States, with a projected population increase of 20.3 percent between 1990 and 2000, following Arizona, Nevada (21.1 percent), and New Mexico (20.6 percent).

During the decade of the 1990's, 13 States are projected to lose population. Iowa and West Virginia would show the largest population declines, each losing over 7 percent of their population. The other States

projected to lose population are North Dakota, Pennsylvania, Wyoming, Nebraska, Ohio, Montana, Indiana, Wisconsin, Michigan, Kentucky, and Illinois.

During the 1995 to 2000 period, Florida and Pennsylvania would be the first States to experience an excess of deaths over births (table 4). However, the high net immigration level projected for Florida more than compensates for this natural decrease, and the State would continue to register a large population increase. Pennsylvania, however, would show population declines with its high levels of net outmigration coupled with its natural decrease.

The first decade of the 21st century would find Hawaii (15.9 percent) and Arizona (15.2 percent) to be the fastest growing States. Other States projected to grow substantially above the national average are New Mexico, Nevada, Florida, and Georgia (table F and figure 3). During the 2005-10 period, West Virginia would join

Pennsylvania and Florida as the only States projected to have more deaths than births (table 4).

Age Distribution

Trends, 1986 to 1990. In general, the projected changes in the age distribution among the four regions mirror the changes projected for the United States (table G). During the remainder of this decade, all four regions are projected to experience increases in the pre-school-age population. The population aged 5 to 17 will increase slightly from 45.1 million in 1986 to 45.6 million by 1990. However, the projected movement of school-age persons out of the Northeast and Midwest Regions would lead to decreases in this age group for these regions. In the South, between 1986 and 1990, the number of children aged 5 to 17 is projected to increase by 291,000, while in the West, the number in this age group

Source: Derived from Table 1.

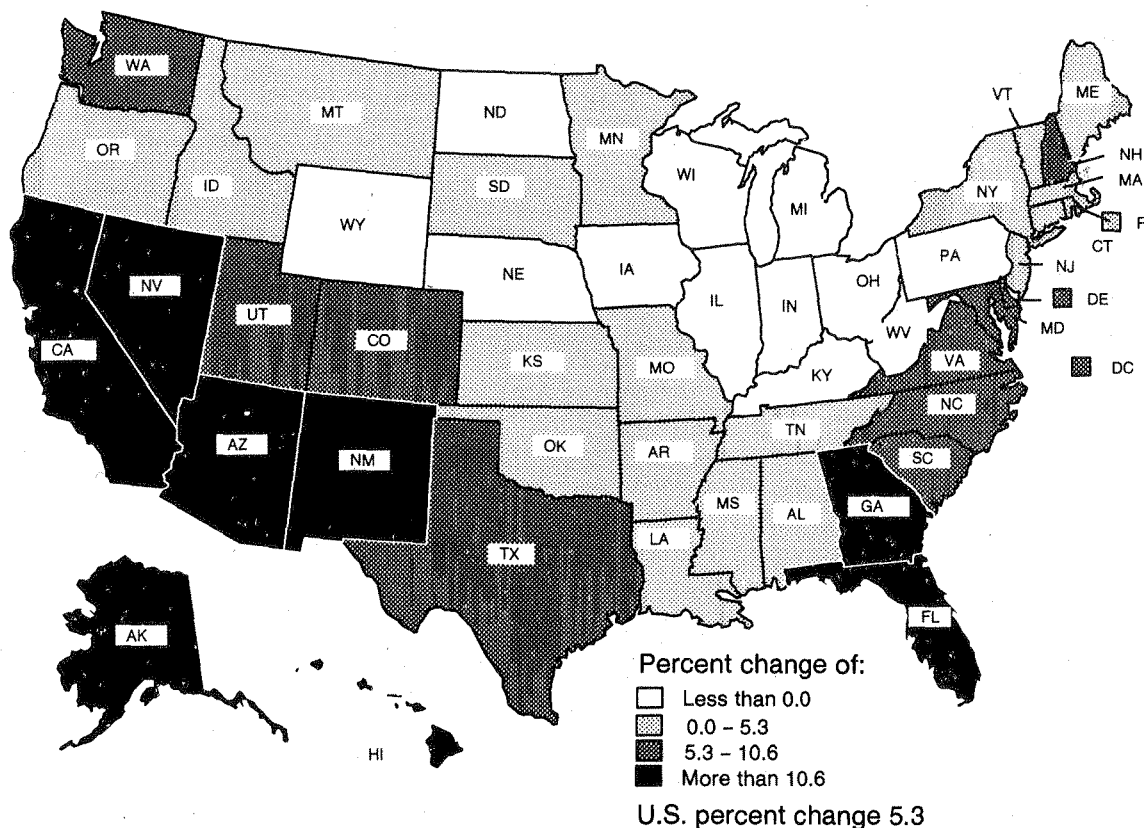

would increase by almost 663,000. Reflecting the overall changes in the age structure of the United States, all four regions would experience a decline in the young adult population (aged 18 to 24) and increases in the population aged 25 to 44 and 45 to 64. Although the Baby Boom cohorts do not move into the 65-and-over age group until well into the next century, between 1986 and 1990 all four regions of the United States are projected to show population increases in this age group.

Of the four regions in 1986 and 1990, the Northeast would have the highest proportion of its population in the 65-and-over age group (table H). It would also have the lowest proportion in the younger groups, under 5 and 5 to 17. Compared with the other regions, the West

would have a higher proportion of its population in the youngest age group and a lower proportion in the oldest group.

Trends, 1990 to 2000. During the last decade of this century, the numbers of children under age 5 are projected to decline by 1.5 million, while the numbers of school-age children would increase by over 3 million (table G). These trends are pervasive in all four regions. The number of young adults aged 18 to 24 is projected to decline in all regions except the West, where the immigration of young persons would compensate for the natural shifts in age structure; the number of persons aged 18 to 24 in the West is projected to increase by almost 400,000. While the population in the 25 to 44 age group is projected to decline in the Northeast and

Figure 3. Projected Percent Change in State Populations: 2000 to 2010

Midwest, the numbers in this age group are projected to increase in the South and West. The maturing of the Baby Boom is reflected in the growth in the population aged 45 to 64 between 1990 and 2000 for all four regions of the country. By 2000, the Northeast would still have the oldest age distribution, while the West would continue to have the youngest (table H).

Trends, 2000 to 2010. Between 2000 and 2010, the numbers of children under age 5 are projected to remain constant in the United States, while declining in the Northeast and Midwest and increasing in the South and West (table G). The numbers of school-age children would decrease in all four regions with the most notable decrease occurring in the Midwest. During this period, the aging of the Baby Boom cohorts is reflected in the declines for the population aged 25 to 44 and increases in the age group 45 to 64. By the year 2010, the Northeast, Midwest, and South all would have approximately 14 percent of their population in the oldest age group. The West would continue to have the youngest age distribution with less than 13 percent of its population age 65 and over.

Dependency ratio. All of these changes in the age structure are reflected in the dependency ratio (table I). This ratio shows how many young and elderly there

would be for every 100 people of working age, those aged 18 to 64. During the next 25 years, for all four regions, the dependency ratio is projected to decline as the proportion of the population of working age rises. In 1986 and 1990, the Northeast would have the highest elderly dependency ratio, but its low youthful dependency ratio would offset the high elderly rate making its overall dependency ratio the lowest among the four regions. Through the year 2000, the Northeast is projected to continue to have the highest elderly dependency ratio. By 2010, the elderly dependency ratios in the South and Midwest would be comparable to the ratio in the Northeast. In 1986 and continuing through 2010, the Midwest is projected to have the highest overall dependency ratio.

Median age. The aging of America is also shown by the increase in the median age projected over the next 25 years (table J). By 1990, the median age of the United States is projected to rise to 33.0 years, an increase of 1.3 years since July 1, 1986. The Northeast's projected median age of 34.5 would be over 1.6 years greater than the median age in the Midwest and South. The younger age structure in the West is evidenced by its lower projected median age of 32.3 years. Florida would continue to be the State with the highest median age (table 5). Its projected median age of 37.4 in 1990, is

Source: Derived from table 5.

over 2 years greater than the next "oldest" State, Pennsylvania with a projected median age of 35.1 years. Alaska and Utah would be the only States to have a median age of less than 30 years. Utah's high birth rates would make it the youngest State with a median age in 1990 of 25.7 years.

By 2000, the range in median ages is projected to narrow. The Northeast would continue to have the highest median age of 37.6 years (table J); the Midwest and South would have the same median age—36.5 years. Florida would continue as the "oldest" with over one half of its population above the age of 41, and Utah

would still have the lowest median age with more than 50 percent of its population under 30 years of age (table 5).

The median age of the Northeast Region is projected to climb to 40.3 by 2010. The South would become the second oldest region with a median age of 39.4 years, and Utah would still be the only State with a median age less than 30 years (27.6 years).

Trends for Race Groups

Table K shows the projected future changes in the racial composition of the regional populations. At the time of the 1980 census, Blacks constituted 10 percent

of the population in the Northeast, 9 percent of the population in the Midwest, and almost 19 percent of the South's total population. In 1980, Blacks constituted less than half of the Black-and-other-races population in

the West; this is primarily due to the high concentration of Asian and Pacific Islanders in the West.

Between 1980 and 2010, the Black population is projected to increase at a rate more than twice as fast

Source: Table G.

as the White population. During this time period, the Black population would increase by 45 percent, compared with the 17 percent growth projected for the White population. Because of their higher rates of growth, the Black population as a proportion of the total population is projected to increase in all four of the Census regions. By 2010, Blacks would constitute almost 14 percent of the total population. In the South, the proportion of Blacks is projected to increase to almost 20 percent, while in the Northeast and Midwest, the proportions are projected to increase to 13 percent and 12 percent, respectively. In the West, Blacks would constitute 6 percent of the population.

By the year 2010, the Nation's Black population is projected to number almost 39 million, an increase of over 12 million since 1980. The White population would

**Table J. Estimates and Projections of the Median
Age, for Regions: 1986-2010**

(As of July 1)

Year	United States	North- east	Mid- west	South	West

1990.....	33.0	34.5	32.9	32.8	32.3
2000.....	36.5	37.6	36.5	36.5	35.3
2010.....	39.0	40.3	38.8	39.4	37.4

Source: Table 5.

be almost 229 million. Under these projections, the number of Blacks living in the South in 2010 is projected to be over 20 million, an increase of more than 6 million since 1980. Much of the growth in the Northeast and Midwest Regions would be in the Black population. Between 1980 and 2010, more than one-half (58 percent) of the growth projected for the Northeast occurs in the Black population. In the Midwest, the White population would decline by almost 2.5 million, while the Black population would increase by over 1.6 million. By 2010, the number of Blacks living in the Midwest and Northeast would be almost identical (7 million). In the West, where Blacks constitute less than half of the Black-and-other-races population, the Black-and-other-races population would increase by over 7 million persons between 1980 and 2010. Because of the impact of immigration from abroad, almost 75 percent of this growth would occur in race groups other than White and Black.

METHODOLOGY

Overview

These projections were prepared using a cohort component method whereby each component of population change—births, deaths, domestic immigration, domestic outmigration, international immigration, and international outmigration—is projected separately for each birth cohort by sex and race.⁴ Although this basic framework is the same as in past projections, these projections represent a major advance in our state population projections methodology. The major innovations include:

1. The projection of annual population by single years of age instead of the projections by 5-year age groups for every fifth year.
2. The use of State-to-State migration flows rather than net migration, or gross immigration and outmigration.
3. The tying of migration projections to the administrative data used in the State current population estimates program to provide more recent information as well as the possibility of updating the migration data during the intercensal period.
4. A time series analysis of recent annual trends in migration streams to add a dynamic element to our migration projections, rather than the past practice of holding migration rates constant.
5. The use of State differentials in survival rates based on the 1980 decennial life tables.
6. The use of State differentials in the timing patterns of fertility based on 1980 birth and population data.

The cohort-component method is based on the traditional demographic accounting system:

$$P_1 = P_0 + B - D + DIM - DOM + IIM - IOM$$

where:

P_1 = population at the end of the period

P_0 = population at the beginning of the period

B = births during the period

D = deaths during the period

DIM = domestic immigration during the period

DOM = domestic outmigration during the period

IIM = international immigration during the period

IOM = international outmigration during the period

⁴The race groups projected are White, Black, and all other races. Because of limitations in the data and methodology and consistency with the national projections, separate projections for each of the individual other races i.e. Asian and Pacific Islanders and the American Indians were not developed. Because of these same factors, projections of the Hispanic population by State were not developed.

In order to generate population projections with this model, we need separate data for each of these components. The assumptions and procedures by which these data are generated by single year of age, sex, and race are described in the sections which follow. In general, the assumptions concerning the future levels of fertility, mortality, and international immigration are consistent with the assumptions developed for the national population projections to be published in Current Population Reports, Series P-25, No. 1018.

Once the data for each of the components have been developed, it is a relatively straightforward process to apply the cohort-component method and produce the projections. For each projection year, the base population for each State is disaggregated into the three racial categories (White, Black, other races), by sex and single years of age (age 0 to 85 and over). The next step is to survive each age-sex-race group forward 1 year using the pertinent survival rate. The internal redistribution of the population is accomplished by applying the appropriate State-to-State migration rates to the survived population in each State. The projected out-migrants are subtracted from the State of origin and added to the State of destination (as immigrants). The appropriate number of immigrants from abroad is then added to each group. The population under age 1 is created by applying the appropriate age-specific birth rates to the females of childbearing age. The number of births by sex and race are survived forward and exposed to the appropriate migration rates to yield the population under age 1. As a last step, the final results of the projection process are adjusted to be consistent with the national population projections by single years of age, sex and race. The entire process is then repeated for each year of the projection. A more complete discussion of each of the components follows.

Base Population

The base population of these projections is the estimate of the July 1, 1986, resident population of states by sex and single years of age as published in Current Population Reports, Series P-25, No. 1010. However, in order to begin the projection system, the base population of each State must be further disaggregated into the three racial categories. Such detailed information is only available for April 1, 1980. The race classification from the 1980 census used in these

projections is not the same as used for census publications. The census counts were modified to be consistent with the Office of Management and Budget categories because of differences in the reporting of race between the 1980 census and other sources of administrative data such as births and deaths.⁵

In order to generate the detailed race information for each State on July 1, 1986, the modified census counts for each race on April 1, 1980, are carried forward to July 1, 1986, with the basic cohort-component approach previously described. The appropriate mortality, fertility, international immigration, and State-to-State migration rates are used. The initial estimates of State population by race for July 1, 1986, were further adjusted to be consistent with both the July 1, 1986, estimates of the resident population of States by sex and single years of age and the 1986 estimates of the resident population of the United States by sex, race, and single years of age.⁶

The population data shown in this report are for the resident population of each State. They include the members of the Armed Forces where they reside at their duty station. They exclude Armed Forces overseas and thus do not match the published national projection totals in P-25, No. 1018. Because of the marked differences in migration behavior exhibited by persons in the military, the projection of the military population is handled separately. Prior to the first step in the projection cycle, the military population in each state by sex, race, and single years of age is subtracted from the resident population. After the application of the appropriate mortality, fertility, international immigration and State-to-State migration rates, the military population is added back to the State population. For these projections, the estimates of the military population in each State are assumed to remain constant at the levels shown in table A-1.

Mortality

The assumptions about future levels of mortality used in these projections are consistent with the middle series mortality assumptions used in the national population projections.⁷ In general, these projections assume a slight increase in overall life expectancy from 75.0 in 1986 to 77.6 in 2005 and 81.2 in 2080. The national level projections provide annual projections of the survival rates by single years of age, sex and race for each

projection year 1986 through 2080. However, in order to prepare the projections at the State level, an additional assumption relating to State differences in mortality was necessary. In previous State projections, no differences in State mortality were incorporated and the national survival rates were used for all States. However, with the increasing importance of projections of the elderly population, and the availability of decennial life tables by State the validity of this assumption was re-examined. For 1970 and 1980, there was considerable variation among states in the life expectancies. This variation was also present within the various sex-race groups. (See table A-2). Given these findings for this set of projections, data from the 1979-81 decennial State life tables developed by the National Center for Health Statistics are used to incorporate existing State differentials into the mortality assumptions.⁸ Throughout the projection period, we assume that the existing patterns of State differentials in mortality remain unchanged.

As a first step in the projections of mortality, the data from the 1979-81 State life tables are used to develop State survival rates for 1980 by single years of age, sex and race. State life tables for the White population were available for all States. However, for many States, NCHS did not develop life tables for the Black population because it was so small. For the States where a life table for the Black population was available, those data were used to calculate survival rates by single years of age and sex for the Black population in 1980. For the remainder of the States, the differentials in the survival rates for the White population are applied to the 1980 U.S. survival rates for the Black population.

The next step of the mortality projections involved projecting the initial sets of State survival rates by single years of age, sex and race to 1986 and each year 1987 to 2010. To project the rates forward, assuming that the state differentials remain constant, the projected annual change in the national survival rates by single years of age, sex and race for each year 1980 to 2010 is applied to each set of State rates.⁹

The National Center for Health Statistics does not prepare separate life tables for race groups other than White and Black and there are no national level projections of survival rates for the "other races" population. Since we did not have sufficient data to make a separate assumption for this race group, the State survival rates for the White population are used for the other races population. This is the same assumption used in the national projections.

International Migration

For this set of State population projections, foreign and domestic migration components are projected separately. In general, assumptions on the overall levels and the age, sex, and race distribution of the international migration components are consistent with the levels and distributions used in the current set of national projections. These projections assume a decreasing level of net international migration from an annual level of 600,000 through 1988 linearly decreasing to 500,000 by 1998 and remaining at that level for the remainder of the projection cycle. This annual net international migration assumption is composed of approximately 160,000 emigrants, and 760,000 immigrants (decreasing to 660,000).¹⁰

The foreign migration component is further disaggregated into the following components: total foreign immigration, emigration, and the flows of migrants between the United States and Puerto Rico. The age, sex, and race distribution of the various international migration components are based on the most recent data available. For total foreign immigration, we used the appropriate average age-sex-race distribution found in Immigration and Naturalization Service (INS) data for the July 1, 1980, to July 1, 1985, period.¹¹ The composition of the emigrant population is based on the existing pattern developed at the Census Bureau for the years 1960 to 1970.¹² Puerto Rican migrants were distributed according to the age-sex pattern of net movement from 1975 to 1980. Once the overall level and the age, sex, and race distribution of each of the international migration components are determined, the components are distributed to each of the States.

Emigration

For the first time in the Census Bureau's State projections, rates of emigration are applied to the base population of each State to develop the number of emigrants leaving each State. The emigration rates are based on the assumption used in the national-level projections of 160,000 emigrants leaving the United States each year. The foreign-born population comprise the largest share of the emigrant population.¹³ In order to compute the rates for each State, the distribution of 160,000 emigrants by age, sex, and race is allotted to

¹⁰This level of immigration is roughly consistent with current levels of legal immigration and 200,000 annual undocumented immigration.

¹²Robert Warren and Jennifer Marks Peck, "Foreign-Born Emigration from the United States: 1960 to 1970", *Demography*, Vol. 17, No. 1 (February 1980).

¹³*Ibid.*

States on the basis of the distribution of the foreign-born population in the 1980 census. Using this distribution as the numerator and the total 1980 population of each State as the denominator, a rate of emigration was calculated for each State. Although the rates of emigration are assumed to remain constant throughout the projection period, the number of emigrants from each State and the total numbers from the United States change throughout the projection period as a result of the projected changes in the base population of each State. Table A-3 shows the estimated number of emigrants leaving each State in 1985-86.

Flows Between United States and Puerto Rico

Another portion of the overall international migration component is the flow of persons between each State and Puerto Rico. For these projections, these flows are projected using sets of State-to-Puerto Rico and Puerto Rico-to-State migration rates based on 1980 decennial census data on residence in 1975. Although the decennial data are for a 5-year migration interval, they are the only data available on the separate flows of migrants between the United States and Puerto Rico. In order to convert the decennial migration data to a 1-year migration interval, we assume for simplicity, that there is no return or repeat migration and obtain the annual flow by dividing the 5-year flow by 5. These results are then the numerators in the rates and the base populations of each State and Puerto Rico are the denominators of the specific migration rates. In addition, since there are no current data to update this beginning set of rates, we assume they remain constant throughout the projection cycle. Even so, the total number of persons moving between the United States and Puerto Rico changes throughout the projection period because of projected changes in the base population of each State and Puerto Rico. Table A-3 shows the annual flow of migrants between each State and Puerto Rico for 1985-86.

Total Foreign Immigration

The remaining components of international migration consist of legal aliens, undocumented aliens, and the net movement of U.S. citizens. For convenience, we will refer to this component as total foreign immigration. However, unlike the total emigration and Puerto Rico components of international migration which are sums of the calculations at the State level, the total number of foreign immigrants entering the United States was calculated prior to the distribution to each State. For these projections, the net international migration by age, sex, and race is assumed to equal the numbers used in the national projections. Given the national total and the projected emigrants and net movement between the

United States and Puerto Rico already calculated in the model, the total number of foreign immigrants entering the United States can be calculated as a residual.

Once the projected foreign immigration to the United States is calculated, it must be distributed to each State. Data from the 1980 census on State of residence of foreign-born persons who entered the United States between 1975 and 1980 are used to distribute the foreign immigrants. This assumption is consistent with the method used to develop current population estimates for States and sub-State areas.¹⁴ Since the 1980 census includes both legal and undocumented immigrants, it provides an adequate basis for distributing foreign immigration to States in the projection. The distribution of foreign immigration to each state is shown in table A-3.

Domestic Migration

Overview and data requirements. At the State level, internal migration is the most important and complex component of population change. In general, it is also the component that shows the greatest degree of fluctuation. Unfortunately, migration data are often the least timely and least comprehensive of the population data sets. For preparing "state of the art" demographic population projections, a complete migration data set should include timely, up-to-date information on in- and outmigration for demographic and geographic disaggregations of the total population. Unfortunately, no single U.S. data source currently meets all these requirements.

In the absence of complete information, there are several alternatives. One alternative is to compromise the methodology to accommodate the available data. Another alternative is to devise techniques to extract and combine the maximum information from available data sets to produce a "synthetic" data set.

At the time of the last set of State population projections, detailed tabulations of migration from the 1980 decennial census were not yet available.¹⁵ Those projections utilized a net migration projection system with data developed as a residual using the 1970 and 1980 decennial censuses population counts and vital statistics data. The residual rates of net migration were applied to the base population of each State to develop the projections of net migration. Using this type of approach, States with net immigration would continue to grow and in future decades automatically receive larger and larger numbers of immigrants. However, states with net outmigration would be either growing very slowly or declining, thus contributing fewer and fewer numbers of outmigrants. As a result, the sum of all interstate migration eventually becomes unbalanced with this

procedure and requires greater and greater adjustments to achieve a national balance. A complete discussion of the inherent problems in a net migration system are discussed in Current Population Reports, Series P-25, No. 937.

Multi-State projection or demographic accounting systems solve many of the faults of a net migration approach.¹⁶ Place-to-place migration data can be used to model migration flows between States explicitly. The rate of moving from one origin State to one destination State is calculated and applied to the base population of the origin State. Using this approach in a projection system, the potential number of immigrants to a State can be linked to the geographic as well as the age, sex, and race distribution of the population. The use of State-to-State migration rates also ensures that the total for the nation of all projected internal outmigration and immigration is zero, a necessary ingredient of any multi-State model.

However, in order to be used in such "state-of-the-art" methods as multi-State demographic accounting, a migration data set should meet the following criteria:

1. Migration should be expressed as a destination-specific, out migration rate. In order to construct these rates, the data base must use State-to-State migration streams applied to a base period population.
2. Each of these streams should be disaggregated by the major demographic dimensions (e.g., age, sex, and race).
3. The migration data must be available for a 1-year migration interval. This is not a general requirement, but is necessary for cohort-component projections done on a yearly basis.
4. The base data should be available on an annual basis for a substantial number of time periods, to add a more dynamic element to the projection of migration rates. Traditional multi-State models and many of the former methods used at the Census Bureau assume that the calculated migration rates remain constant throughout the projection period.
5. Some procedure to update the rates on a timely basis should be available. This requirement allows for the projections to be updated so that current estimates do not make the projections obsolete very quickly.

¹⁴Current Population Reports, Series P-25, No. 998.

¹⁵Current Population Reports, Series P-25, No. 937.

¹⁶Andrei Rogers and Frans J. Willekens, *Migration and Settlement*, 1986, Dordrecht, Netherlands: D. Reidel Publishing Co., 1986.

6. The migration data must be consistent with the population base of the projection, which is a census-level estimate.¹⁷

Unfortunately, no single U.S. data source currently meets all six of the above conditions. In the United States, there are three major sources of migration data: national surveys (e.g. March supplement to the Current Population Survey), administrative data sets (e.g., migration data developed from matched tax returns¹⁸), and the decennial census. Each data set provides partial information and contains unique characteristics (See figure 4). Thus, for these projections, it was necessary to create a "synthetic" data set incorporating data and features from all three sets.¹⁹ The three specific data sets used in these projections include: 1) the migration data from the March supplements of the 1976, 1980, and 1981 Current Population Surveys (CPS); 2) the State-to-State migration flows by age, sex and race derived from the 1980 decennial census; and 3) the annual State-to-State migration flows for the period 1975-76 to 1985-86 derived from the matched tax returns.²⁰

A set of "synthetic" data has been created that incorporates the migration levels implied by the administrative data, and the demographic dimensions implied by the decennial and CPS data. In order to develop sets of State-to-State migration rates by single years of age, sex and race for each year in the projection cycle, the following steps were used:

1. Development of base-year migration data
2. Updating the migration matrix
3. Projection of the migration matrix

Each of these steps is discussed in more detail below.

Development of base-year migration data. The first step in this process is to develop an appropriate beginning migration matrix of annual State-to-State migration rates by age, sex, and race. The 1975-80 decennial migration data provide a good beginning framework. However, while the census data provide good State-to-State data by age, sex, and race, these data cover a 5-year time period. The projections model, however, requires the equivalent migration rates for a 1-year time frame.

¹⁷This is not a general requirement, but must be met for the Census Bureau production framework.

¹⁸See Current Population Reports, Series P-25, No. 957 for a more complete discussion of the development of migration data from the tax return data available from the Internal Revenue Service.

¹⁹See Long and Wetogon, "Creating Annual State-to-State Migration Flows," Paper presented at the 1986 Population Association of America, for a complete discussion of the three data sets.

²⁰The data for 1977-78 were not used because of processing delays in creating these special files.

Given the effects of return and repeat migration, it is not appropriate to simply divide the 5-year rates by 5.²¹ Instead, it was necessary to develop an empirical relationship between the 1-year and 5-year migration data. The results of the questions on residence 1 year earlier in the 1976 and 1981 CPS, were used to develop an estimated average 1-year interstate migration rate for 1975-80 by single years of age. To produce an aggregated 5-year cohort migration rate, the estimated average 1-year interstate migration rates for the appropriate single years of age groups are summed for the 5 years. A comparison of the aggregated cohort migration rate with the corresponding 5-year interval migration rate for the 1975-80 period from the 1980 CPS provides information by single years of age on the relationship of 1-year and 5-year migration data.

Once the relationship between 5-year and 1-year interstate migration rates was established using the CPS data, it was relatively straightforward to apply this relationship to the decennial migration data. The ratios between the 5-year and 1-year interstate migration rates within a given age group were applied by age to each race-sex specific State-to-State migration rate from the decennial data.

In order to incorporate the migration levels implied by the administrative data with the demographic dimensions implied by the decennial and CPS data, a further refinement to the beginning migration matrix was required. The beginning 1-year matrix was adjusted to the average State-to-State migration flows implied by the administrative data for the 1975-80 period.

Updating the migration matrix. The next stages of development involve a method to update the beginning migration matrix to reflect the current or projected shifts in migration patterns. The administrative data on migration from matched tax returns provide the best source of information about the change in migration trends since the 1975-80 period.

The updating process adjusts for the change over time in each State-to-State flow. For years in which the State-to-State rates are available from the administrative records (i.e., 1975-76 to 1985-86), a ratio of the current State-to-State rate to the average of the 1975 to 1980 values is computed. The migration matrix is updated by multiplying the ratio times the 1975-80 average for every age-sex-race group in the synthetic migration matrix. Table A-4 shows the estimated State-to-State flows that result from applying the updated 1985-86 matrix of migration rates to the base population of each State.

²¹See Long, John, and Celia Boertlein, "Using Migration Data from Different Intervals, 1988" Population Division Working Paper; and Philip Rees, "The Measurement of Migration from Census Data and Other Sources," *Environment and Planning*, Vol. 9, No. 3, 1977.

Figure 4. Dimensions of Underlying Migration Matrix

Projecting the migration matrix. For projection years beyond the last date of annual migration data (beyond 1985-86), some method of extending the State-to-State rates forward in time on an annual basis is necessary. For this set of projections, a dynamic element has been added to the migration projections instead of the past practice of holding the current migration rates constant.

In past projections, an average migration rate over a 5- or 10-year period was all that was available. In this series, however, we have annual data on State-to-State migration rates of the total population (without age, sex, and race detail) for an 11-year period. The strategy calls for projecting these rates for the total population and applying these changes to the age, sex, and race distribution of migration rates determined above.

Projecting total State-to-State migration rates. There are a number of ways of using the annual time series of 2,550 State-to-State migration rates (51 States of origin x 50 States of destination) for 1975-76 through 1985-86 from the matched tax returns. The projection method for these migration rates should fulfill four objectives identified in discussions with users and members of the Federal State Cooperative Program for Population Projections. These objectives are:

1. To use as long a time period as possible so that random or abnormal fluctuation in the rates could be averaged out.
2. To use the most recent data available to incorporate a shift in a State's migration patterns.
3. To continue recent changes in the migration rates so that emergent trends can be captured.
4. To force convergence in the migration rates so that instabilities will be changed and a return to some equilibrium value assured.

While all of these objectives are important and each have their merits, they often conflict. Many of the suggested procedures for projecting the migration rates would meet one or two objectives but not others. An average (mean) of all the years would meet conditions 1 and 4 but not 2 and 3. Using the last year only would meet condition 2. Using the most recent rate of change would meet condition 3 by emphasizing an improving or deteriorating trend in migration but would ignore earlier patterns in the period and thus ignore conditions 1 and 4. Converging net migration to zero would meet condition 4 but none of the others. In future revisions, multiple series can be developed by using alternative projection procedures that emphasize different objectives.

This set of projections required a procedure that attempts to combine the four conditions into a single projection of the migration rates. While a Box-Jenkins ARIMA process might be devised to meet all four conditions, the short time series and the presence of missing data called for another method. The procedure chosen to project the State-to-State migration rates for these projections was a composite of procedures that provide a compromise between the four desired objectives. The method emphasizes the mean when no trend is apparent in the data, uses the last data point as a point of departure to prevent any discontinuities in the series of migration rates, and provides a mechanism to modify extreme trends that would tend to introduce instability in the set of migration patterns.

For each of the State-to-State rates, the trend over time is extracted using a linear regression model based on the historical time series of data covering the 1975-86 period. The regression should not be viewed as an attempt at explanatory analysis but rather as a forecasting tool to meet the objectives cited above. Moreover, the results of the regression are not used to set every future year but only provide an estimate of the 1994-95 migration values. Years between 1985-86 and 1994-95 are determined by a linear interpolation between the two values. This procedure avoids the discontinuity that would arise from using the regressed values for intermediate years. For years between 1994-95 and 2009-10, the migration rates are assumed to remain constant at the 1994-95 values. The regression model is thus allowed to operate for only a few years to reduce the risk of instability that could arise from the limited data set.

This procedure for projecting the migration rates represents a compromise of the various objectives. In those cases where there is little or no linear trend apparent in the data, the measure of association and the value of the slope coefficient approach zero.²² Under these conditions, the model assumes that the value of the State-to-State migration rates do not change over time and that the best prediction of the future values is the mean of the historical data fulfilling condition 1.

In those cases where the model identifies a linear trend over time, the regression analysis should provide the leeway for a further extension of the emergent trend fulfilling condition 3. However, the regressions based on time trends alone can, under some circumstances, produce unrealistically extreme values. In order to place some limits on the linear regression projections, the projected 1994-95 values were compared with the means of the historical data sets and the last observed values (the 1985-86 migration rates). The regression value was used for 1994-95 only if it was within a range of .8 to 1.2 times the mean of the historical data. In those cases, where the 1994-95 value fell outside these limits, the 1994-95 value was set at either .8 or 1.2 times the mean. This modification assures that condition 4 applies.

An exception to this rule was made when the actual 1985-86 and 1994-95 values were both outside the range. In these cases, the 1994-95 value was set equal the 1985-86 level. This exception was permitted so that condition 2 would apply when there had been a major change in past trends.

Combining trend and age, sex, and race detail. Once the annual total State-to-State rates are projected, the next step is updating the initial matrix of State-to-State migration rates by single years of age, sex, and race. For each year 1986-87 to 1994-95, the ratio of the projected State-to-State rate to the average of the 1975 to 1980 values is computed. This ratio is applied to yield a set of projected State-to-State migration rates by single years of age, sex and race. Table A-5 shows the estimated State-to-State flows that result from applying the updated 1994-95 matrix of migration rates to the base population of each State. Since the total State-to-State rates remain constant beyond 1995, the matrix that is developed for 1994-95 applies for every year 1995 through 2010. This entire process yields a set of State-to-State rates by single years of age, sex, and race that incorporates the annual trends implied by the administrative data and the age, sex and race distributions implied by the 1980 decennial data.

²²Draper, N.R. and H. Smith, *Applied Regression Analysis*, John Wiley & Sons, New York: 1966.

Fertility

Projections of the future births in each State are based on 1) the projected number of females of child-bearing age in each State, and 2) an assumption on the rate at which these women will bear children. For each projection year, the first step is to develop an approximation of the female population exposed to the possibility of childbearing. This population is the average of 1) the female population of each race by single years of age from age 14 through age 49 at the beginning of the year, and 2) the same population projected for the next year.

The next step in the projection process is the development of the appropriate age-race-specific fertility rates for each state. The assumptions about future levels of fertility used in these projections are consistent with the revised middle series fertility assumption used in the national population projections.²³ In general, these projections assume a slight increase in the levels of fertility to an ultimate level of 1.8 births per woman. The national projections provide a set of annual age-specific birth rates by race for each projection year. The State projections require an additional assumption about the differentials in these rates by State.

The projected fertility differences across States are based on historical patterns. There is considerable variation in the total fertility rates and the age patterns of childbearing among States for both Whites and Blacks.²⁴ For this set of State population projections, existing differentials in State age-specific birth rates are assumed to remain constant throughout the projection period.²⁵

The initial set of age-specific birth rates is the average of 1979, 1980, and 1981 births by age of mother and race for each State divided by the 1980 census population in each State.²⁶ These initial sets of age-specific birth rates for the White and Black populations in each State are shown in tables A-6 and A-7. Because the data for races other than White and Black are not sufficiently detailed to prepare a separate set of initial age-specific birth rates for each State, we assumed that the State age-specific birth rates for the White population apply to the "other races" population.

To project the State birth rates forward to each year through 2010, annual changes in the projected national birth rates are applied to the individual State rates

²³See Current Population Reports, Series P-25, No. 1018 for a complete discussion of the method used to develop these assumptions.

²⁴Age-specific birth rates for states are derived from fertility data published by the National Center for Health Statistics and decennial census data. For Whites, rates were calculated for 1950, 1960, 1970, and 1980; for Blacks, 1970 and 1980 only.

²⁵See O'Connell, Martin, "Regional Fertility Patterns in the United States: Convergence or Divergence?", *International Regional Science Review*, Vol. 6, No. 1, 1981.

²⁶For births by age and race of mother by State, see National Center for Health Statistics, *Vital Statistics of the United States, 1979, 1980 and 1981, Vol 1, Natality*.

calculated in 1980 to obtain annual projections of the age-specific birth rates for each State. The total number of projected births is calculated as the product of the state age-race-specific birth rates times the appropriate female population. Once the number of births is obtained for each projection year, the national race-specific sex ratio at birth is used to divide the births into males and females. This yields births for each race-sex group during the projection year. As a final step, the number of births by sex and race are survived to the end of the year, and "migrated" from State to State and moved between the United States and abroad using the procedures described above. The result is the projected population under age 1 on July 1 of each projection year for every race-sex group in every State.

Adjustment to National Projections by Race, Sex, and Age

A final step in the projection model involves adjusting the sum of the State populations by age, sex, and race to the middle series projections of the population of the United States.²⁷ Although the State projections system is consistent with the projected national trends in fertility and mortality, the State population projections model incorporates State differentials in mortality and fertility. Thus, the total number of births and deaths calculated in the State projections system does not necessarily equal the numbers developed in the national projections system. The State populations by age, sex, race are adjusted to agree with the middle series national projections of the resident population which are census-level projections using the inflation-deflation procedure.²⁸ Therefore, the sum of the annual components of change shown in table 4 may not agree with the annual changes in the total population. The difference represents the adjustment necessary to bring the sum of States into agreement with the projected U.S. total and is generally small.

RELATED REPORTS

The table that follows lists other Current Population Reports containing estimates and projections related to those shown in this report and specifies the years for which consistent data are provided.

²⁷See Current Population Reports, Series P-25, No. 1018 for a discussion of the methodology used to develop these projections.

²⁸For a discussion of the inflation-deflation methodology, see Current Population Reports, Series P-25, No. 1022.

State estimates:		
By age and sex, and component	1980-87	1024
By age and sex, and component	²⁹ 1980-86	1010
By age and component	1970-79	998
U.S. projections:		
by age, sex, and race and Component	1988-2080	1018

AVAILABILITY OF MORE DETAILED DATA

The basic product of our methodology is a set of unrounded population data by single years of age, sex, and race for each year, 1988 to 2010, for each State. Most of these data are not published, but all of them are available from the Bureau of the Census in machine-readable form. Further information may be obtained by writing to the Chief, Population Division, Bureau of the Census, Washington, D.C. 20233.

SUMMARY AND LIMITATIONS OF PROJECTIONS

The State population projections in this report are what the future population by age, sex and race would be, given the stated assumptions about fertility, mortality, international immigration, and internal migration trends. They are the first projections to be produced by single years of age for individual calendar years. They are also the first to use an enhanced methodology that incorporates the annual State-to-State flows of migrants from matched tax returns together with the demographic detail from the Current Population Survey and decennial census. Since the CPS and decennial information are derived from sample data, they are subject to sample variability.³⁰ Much of the methodology and assumptions are in early stages of development. We are interested in the reaction and comments of users to the methodological refinements of these projections. We are also interested in the comments on quantity and format of information presented in this report. If you have suggestions or comments, please send them to:

Chief, Population Division
U.S. Bureau of the Census
Washington, D.C. 20233

²⁹The projections by age and sex shown in this report are consistent with the 1980 to 1986 estimates of state population shown in P-25, No. 1010. The 1980 to 1987 estimates were not available to be used in these projections.

³⁰Estimated standard errors and a detailed discussion of the accuracy of the data can be found in Appendix B, Current Population Reports, Series P-20, No. 377 and in Appendix D of the 1980 Census of Population, Detailed Population Characteristics, PC80-1-D.

ROUNDING OF PROJECTIONS

The population projections in the tables have been rounded to the nearest thousand without being adjusted to group totals, which are independently rounded.

SYMBOLS

In this report, a dash (-) means zero or rounds to zero; * means that the detailed data for the Black population are not shown for states where the total Black population on April 1, 1980, was less than 25,000; "NA" means not available, and a minus sign preceding a figure denotes decrease.

- Represents zero. ¹These time periods vary in length; April 1, 1980, to July 1, 1986, represents a 6.25-year period; July 1, 1986, to July 1, 1990, represents a 4-year period. The remaining intervals shown are all 5-year periods. ²These components do not include the adjustment to bring the sum of the State projections by age, sex, and race into agreement with the national population projections. Thus, the net sum of the components will not equal the net change in population. ³The net migration data shown for April 1, 1980, to July 1, 1986, include the internal and international migration components. Separate data are not available for this period. ⁴The internal migration component for regions, divisions, and States includes the net movement of persons to the Armed Forces overseas. For the U.S. total, this component reflects only the net sum of internal migration which is zero.

Table 5. Total Population of Regions, Divisions, and States by Age and Sex: 1980, 1986, and 1990-2010

Numbers in thousands. As of July 1, except as noted

NA No projection is available for that date.

Note: These projections were prepared by the individual State agencies shown in appendix B. Each State employs its own methodology and base data; thus these individual State projections are not necessarily consistent with each other, a July 1 date, or with Census Bureau methods. For information on methodology and for more detailed results, contact the State agency shown in appendix B.

Appendix A. Detailed Assumptions

Table A-1. Assumed Military Population in Each State, by Race: 1987-2010

(Rounded to thousands)

Region, division and State	Total	White	Black	Region, division and State	Total	White	Black
United States	1,714,000	1,342,000	302,000	West North Central:—Con			
Northeast	110,000	93,000	14,000	South Dakota	6,000	6,000	1,000
