ABSTRACT

The purpose of this study was to investigate the differences between the administrative record data for establishments which were non-respondents to the 1977 Censuses of Wholesale Trade, Retail Trade or Selected Services and the "reported" data for these establishments acquired by intensive follow-up procedures.

The table below summarizes the findings. The ratio estimator of "reported" data to administrative data exceeded one for all trade areas and for each variable studied. This pattern was also observed when the ratio estimators were calculated for single unit establishments and multi-unit establishments separately.

Ratio: "Reported"
Data to Adminis-
trative Data

	Wholesale	Retail	Services
Sales/Receipts	1.038 (.0355)	1.053* (.0262)	1.113** (.0296)
Annual Payroll	1.103** (.0315)	1.041* (.0192)	1.068* (.0278)
IQ Payroll	1.134** (.0343)	1.054** (.0204)	1.071* (.0287)
IQ Employment	1.181** (.0358)	1.145** (.0270)	1.252** (.0361)

*Significant at the 5% level

**Significant at the 1% level

I. Introduction

The study to evaluate the use of administrative record data in the 1977 Economic Census (DE-1) had several parts. One of these components was the use of administrative data for establishments which were non-respondents to the Censuses of Wholesale Trade, Retail Trade, or Selected Services. Since administrative records were used to impute data for establishments that were non-respondents to the census, the survey was designed to obtain data from a sample of these delinquent establishments and compare certain key data items. These data items were sales/receipts (S/R), annual payroll, first quarter (IQ) payroll and first quarter employment. The sample was designed and selected in late 1978 and early 1979. The telephone interviewing began in March, 1979. Data collection lasted throughout all of 1979, terminating in the beginning months of 1980. The data were compiled on actual census forms and were eventually keyed from the forms onto computer tape. Analysis of the data began in June 1980.

There is some reason to suspect that the data collected were not completely accurate as the data were collected by telephone interviewing and the universe was those establishments which had already exhibited their reluctance to respond to the Census. However, there is no evidence to suggest that this observation should lead to invalidating the results of the study. While too much faith should not be placed in exact values, however, certain trends are quite clear. Using a ratio estimator of "reported" data to administrative data, there is little doubt that over all the variables studied and for all trade areas, the "reported" data exceeded the administrative data. The differences observed varied widely by the variable in question and the trade area but the employment data clearly showed larger differences than the other variables.

Also, multi-unit establishments displayed this phenomenon much more strongly than did single units for each trade area.

The study used three different data sets for the sampled establishments. These were the administrative data for the establishment at the time a form was mailed, the data carried on the record for tabulation purposes (which was exactly equal to the original administrative data in the overwhelming number of cases) and the data as collected, the "reported" data. Because the administrative data and the tabulated were so often equal, the ratio estimators were computed only comparing the reported data and the administrative data. Delays were encountered in the analysis of the data as the transcription and keying operations were rather error-prone. Despite the editing necessitated by these errors, a substantially "clean" data file was constructed for analysis and tabulation.

II. Sample Design and Selection

The universe for the study was those establishments which did not respond to the 1977 Census of Retail Trade, Wholesale Trade and Selected Services. The universe did not contain establishments in Alaska or Hawaii. Two classes of returns were also excluded from the sample. These were:

1. PMR's - Postmaster Returns. For some reason the mailout address was incorrect or the establishment may have gone out of business.
2. Congressionals. These were cases that indicated that a Member of Congress or U.S. Senator had been or would be contacted.

The sample universe was then defined as those establishments with the following check-in actions as of August 1978:

- 1-1 a case was to be returned to follow-up status
- 1-3 a second form was re-mailed as requested by the company but was not sent back to the Bureau
- 1-4 Some correspondence was received, but not a form.
- 1-7 an extension period was granted.

Or no check-in code was present, which indicated that nothing was received from the establishment.

Within each of the three trade areas, the sample was stratified by type of unit, by SIC code, and by annual sales/receipts. In all cases, a systematic sample was chosen within each cell with the sample sizes designed to obtain an approximate 2 1/2% CV on the ratio of reported to administrative receipts.

Creation of the sample listings was a process involving several stages. Unfortunately, an error was made such that the resulting sample did not represent the precise universe that was desired. The six steps which produced the sample were:

1. Using the August, 1978 ESD check-in file as input, those records having a "nonresponse" check-in code were stripped from the file. For single units, the output file contained 434,993 records stripped from the input file of 2,441,896 records. The corresponding numbers for multi-units were 57,500 from 758,312.
2. The files of "non-response" records were then matched to Business Division files to determine which records belonged to the trade areas

chosen for this study. This step yielded 276,713 records for single units and 42,501 records for multi-units.

3. These two files were split into the three Business division trade areas to form the six basic strata for the study.
4. Within each of these six strata (SU versus MU by trade area) it was desired to stratify further by SIC groupings and, within SIC groupings by administrative sales/receipts. In order to use the cumulative square root of frequencies rule to form the boundary points for the stratification by sales/receipts, counts of establishments within each SIC grouping were obtained using intervals of \$50,000 of sales/receipts.

The original plan was to select a cut point, C_t , for a certainty stratum (within a given SIC) and then use the rule mentioned above to determine the remaining cut points $C_1, C_2, C_3, \dots, C_{t-1}$ (the c's in thousands of dollars). For wholesale and services, t was chosen to be 7, for retail, t equaled 9.

During the selection of these boundary points, however, certain records were erroneously eliminated. Thus the results of the study pertain only to this reduced universe. The records removed from the study were those whose administrative S/R were less than \$50,000 or greater than \$16,500,000.

The following table traces the record counts to this point (two counts could not be determined from the documents available).

		Trade Area SPLIT (3)			
	(1) "Non-response" check-in	(2) Match to Business	W	R	S
SU	434,993	276,713	61,216	113,760	101,737
POST S/R STRATIFICATION		171,149	19,932	88,957	62,260
MU	57,500	42,501	NA	NA	11359
POST S/R STRATIFICATION		33,961	6793	19,232	7936

Thus, the single-unit file lost 105,564 records (38%) and the multi-unit file lost 8,540 records (20%).

5. This step sorted the records by SIC class and the S/R administrative data and also amended the S/R boundary code which was clerically determined at the previous step, thus preparing the file for the actual sampling within each of the SIC by S/R cells.
6. The program at this stage selected the actual sample and produced listings of the sampled establishments. The file from the previous stage was used as one input and combined with clerically supplied "start with" figures and the previously determined sample sizes to select a systematic sample from each stratum. This program also amended the sampling weight to the establishment record.

This program was run four times for each of the six basic strata producing an "original" sample and three supplementary samples. These four samples were independent and the extra cases were to be used for those

establishments that eventually become respondents to the census and thus became out of scope to the survey. Recall the initial input file was that file available in August, 1978 which was not a complete file of nonrespondents at that time.

These three supplementary samples were of equal size and smaller than the original sample and while these supplementary samples were used in increasing the total response for the single units, they were not used for the multi-units.

Appendix 1 contains the description of the SIC groupings used in trade area stratification.

Appendix 2 contains tables which show the universe breakdowns, the weights, the original sample sizes and the supplementary sample sizes for each of the six basic strata. For those SU cells where a supplementary sample was applied, the non-integral weights show the effect of these multiple samples for establishments in those cells.

III. Data Collection

The collection of the data was a telephone operation carried out at the Bureau by the clerical staff of the Research Center for Measurement Methods (which has since merged with the Statistical Research Division). Statistical assistants transcribed the data for each telephone interview onto a census form as specified in the mail file, or onto a generalized short form, the NC-X4.

Three thousand seven hundred (3,700) establishments were contacted (it took an average of six phone calls to an establishment to get the required information or another refusal). Of these 3,700, 3,125 eventually resulted

in a completed interview, while 575 became "referrals". These referral cases usually required a letter to be sent to the establishment to provide additional identification not possible over the phone and also to encourage a response.

These 575 referrals generated 154 additional completed interviews, giving a total response of 3,279 establishments. 421 cases were either refusals, impossible to interview because of a change in location or "out of business". The approximate cost of this telephone operation not including staff time, was in the range of \$6,000 to \$8,000.

The census forms for these "reported" establishments were grouped into four general categories for keying. These groups were the three trade areas and the general NC-X4 form. The keying was done in Jeffersonville, Indiana following the same keying specifications used in the Census. These four raw files of data were available by June, 1980.

It was the opinion of several of the statistical assistants who collected the data that often the respondents would provide any number in order to further the interview and that accuracy suffered as a result. A further indication of this phenomenon was a comparison of the distribution of the last digits of the administrative data versus the reported data. Since monetary data were to be reported in thousands of dollars the last three digits of an exact dollar amount were truncated. While the administrative data showed no evidence that the distribution of the last digits differed from the discrete uniform distribution, the reported data was characterized by a concentration of values ending in zero.

This evidence suggests that the reported data were subject to frequent rounding or "ball-park" figures with a resulting loss of accuracy, however, this rounding did not appear to invalidate the data. This phenomenon applied to all of the key data items including employment which was not subject to truncation as the dollar items were.

IV. Data Editing

The keyed files required extensive editing before they were prepared for analysis. The following is a list of those edit procedures which were performed in order to create "clean" data files for each of the trade areas.

- 1. It was common for several multi-unit establishments which were part of the same firm to be reported on the same form. Hence an individual computer record did not always correspond to a single establishment. Also, for these records, the Census File Number (CFN) was entered as ten zeroes in the field which was keyed, while the correct CFN's were included on a different section of the form.
- 2. Since the CFN must be used in connecting reported data to the listed sample establishment, any error in transcribing the CFN from the sample listings to the form or the keying of the CFN from the form to tape caused matching problems. Certain of these unmatched returns were eventually paired to a sample establishment by using the establishment name. Since the establishment name was not keyed this was a time-consuming process.
- 3. Item nonresponse was diminished by checking the keyed data against the actual form for every record. This process also corrected data fields that were incorrectly keyed. This step was done after the forms were

4. Records where the reported first quarter payroll exceeded the annual payroll were listed and corrections applied. This problem was an infrequent occurrence.
5. Duplicates had to be removed. Duplicates were possible not only by contacting a firm twice by mistake, but, by virtue of the supplementary samples chosen, a firm may have been listed twice.
6. It was necessary to identify the correct trade area in which to include the form. The files for the three trade areas did not exclusively contain forms for that trade area, requiring deletion from one file and inclusion into a different file. The entire NC-X4 file needed to be split into the proper trade areas. The following tables show the split of the NC-X4 file and how total returns matched to the original sample sizes.

	Wholesale	Retail	Services	Total
Census Form Returns	498	1168	958	2624
NC-X4 Returns	132	247	276	655
TOTAL	630	1415	1234	3279

Total Returns (Samplesize)	W	R	S	T
MU	216(289)	427(647)	185(287)	828(1223)
SU	414(430)	988(1047)	1049(1203)	2451(2680)
TOTAL	630(719)	1415(1694)	1234(1490)	3279(3903)

Respondents (%)	W	R	S	T
MU	74.7	66.0	64.5	67.7
SU	96.3	94.4	87.2	91.5
TOTAL	87.6	83.5	82.8	84.0

V. Computation of the Ratio Estimators and Their Variances

To compute the ratio estimators and their variances, certain quantities were needed for each independent stratum. These quantities were then summed over the strata to achieve estimates at the KB level for single and multi-units and for a trade area.

For each cell, the basic weight, w , was the integer, k , in the expression $N = nk+q$ for systematic sampling where N = number of establishments in a cell and n the sample size. However, when a supplementary sample was used in a cell, this weight was modified to reflect the additional sample. For example, if a cell used one additional sample, the k of the original sample would be combined with the k^* of the supplementary sample in the following way to produce the weight, w , for the cell. The w in this case would be computed as $(k^{-1} + k^{*-1} - (k \cdot k^*)^{-1})^{-1}$. This is basically the sum of the probabilities of being included in either sample minus the probability of a unit being selected twice, since duplicates were only counted once. Similar expressions were developed for those cells where more than one of the supplementary samples was used.

In addition to these weights for each cell, other values were required to produce the ratio estimate and an estimate of its variance. These were:

1. NUMERATOR= $w \sum r_i$ where r_i is the reported data for an establishment
2. DENOMINATOR= $w \sum a_i$ where a_i is the administrative data for an establishment
3. VARIANCE-NUMERATOR (VN)= $\sum N^2(1-n/N)(2n(n-1))^{-1} \sum (r_{(i)} - r_{(i+1)})^2$
where $r(i)$ represents the reported data in the order that the sample frame was originally listed.

4. VARIANCE-DENOMINATOR (VD)= an expression similar to 3 except using $a(i)$ for $r(i)$.
5. COVARIANCE of the NUMERATOR and DENOMINATOR (CND)= an expression similar to 3 and 4 except using $(r(i)-r(i+1))(a(i)-a(i+1))$ within the summation. Then, for one cell, the ratio estimator is
6. $R = \frac{NUM}{DEN}$ with an estimated variance equal to
7. $R^2 = \left| \frac{VN}{NUM^2} + \frac{VD}{DEN^2} - \frac{2*CND}{(NUM)(DEN)} \right|$

By summing these first five values over the cells, expressions (6) and (7) can be computed for each KB, type of unit, and trade area.

In using these formulas within each cell, the summation is taken over the entire sample for that cell. This required an adjustment to be made for those establishments which were non-respondents to the survey, declared out-of-scope, or eventually became respondents to the Census. This resulted in two sets of ratio estimators being calculated.

Where an establishment fell into one of the classes above, one estimator would use the administrative data value for the "reported" data which was not available. This was a "conservative" estimate as the adjustment would mask differences between the reported and administrative data. The second class of estimators would set both the administrative value and the unavailable "reported" value to zero.

Certain KB's in the Service Industry sample had a sample size equal to 1 for the cells in that KB. For these KB's, the previous variance expressions (3), (4), and (5) do not apply. In these cases, a simple collapsed stratum estimator of variance was used.

Corresponding expressions for these KB's are

$$(3a) \sum_{g=1}^{L/2} [(2N_{g1}N_{g2})/(N_{g1}+N_{g2})]^2(r_{g1}-r_{g2})^2$$

where the summation is over the pairs of cells, of which there were three in these cases as L equaled 6. Again the N represents universe size in a stratum and r is for reported data in a cell.

- (4a) Similar to 3a except a's are substituted for the r's.
- (5a) Again similar to 3a and 5.

Thus, an estimate of the variance at the K3 level was possible with appropriate summations at the type of unit and service industry level.

The occurrence of outliers in the data necessitated further adjustments in the estimation process. The method chosen to adjust for the outliers was to change the reported data for an observation whenever the ratio of the reported data (r) to the administrative data (a) exceeded a given value or its reciprocal. Symbolically, if $r/a > m$, then $r = am$ or if $r/a < 1/m$, then $r = a/m$ where r is the reported value, a is the administrative value and m a predetermined constant. Thus, if m were unity, the degenerate case where each ratio would be set to one would be realized.

Conversely, were m to be set to infinity, no outlier adjustment would occur. Computations were carried out using four values for m: 2.5, 5.0, 7.5, and 1,000,000 (i.e. no adjustment). One further computation was carried out using the factor of 7.5 only. In this case, instead of r being adjusted by the 7.5 factor, r was set equal to a. This outlier adjustment scheme is presented graphically in appendix 3.

By the nature of this process, the variance of the adjusted ratio estimates must be lower than the variance of the unadjusted estimates. For the factor of 7.5, reductions in the area of 50% to 75% were observed by adjusting 2% to 7% of the cases. Less dramatic gains were achieved as the adjustment factor was decreased from 7.5 to 2.5.

VI. Results

Appendix 4 contains the tables upon which the following twelve charts (pages 21-32) are based. These graphs use data at the trade area by type of unit level while the tables contain the detailed SIC level data. Each chart has a similar format with the title giving the trade area and the variable charted. The y-axis, labeled "RATIO", is the value of the ratio estimators. The x-axis labeled "OUTLIER TYPE", consists of seven points of which five contain data values for each of the six lines graphed. Symbols appear at these five points. These five points represent the estimate calculated using no outlier adjustment and the four different outlier adjustments previously discussed. The system used to chart these is described most easily by numbering the x-axis points 1 to 7 starting from the left, with the following pattern:

- 1 - no outlier adjustment
- 3 - outlier factor = 7.5 with reported values adjusted using this factor
- 5 - outlier factor = 5.0 with reported values adjusted using the factor
- 7 - outlier factor = 2.5 with reported values adjusted using the factor

Only one of points 2, 4 or 6 contains a value. This point corresponds to the outlier adjustment procedure using a factor of 7.5 but having the

reported value set equal to the administrative value. This value is charted so that the series is continually decreasing to the right, thus this value can be plotted at point 2, 4, or 6. The lines charted will converge towards unity from points 1 to 7 since each point represents a more stringent outlier adjustment. These points are numbered on the graph with the appropriate outlier factor in parentheses.

These tables also provide the number of sample cases affected by each of the outlier schemes.

6 lines are plotted on each graph and identified in the lower right hand corner. These are:

SUA (symbol = 1, solid line)	Ratio estimator for single units using a non-response adjustment where the reported data is set equal to the administrative data (the "conservative" estimate).
SUZ (symbol = 1, dashed line)	Ratio estimator for single units using non-response adjustment where both the reported data and the administrative data are set equal to zero.
MUA (symbol = 2, solid line)	Same as SUA above, for multi-unit establishments
MUZ (symbol = 2, dashed line)	Same as SUZ above, for multi-unit establishments
SMA (symbol = 3, solid line)	Same as SUA and MUA, for combined single units and multi-units
SMZ (symbol = 3, dashed line)	Same as SUZ and MUZ, for combined units

The solid line representing the "conservative" estimate must always lie closer to one than its corresponding dashed line by the nature of the adjustment. Also the lines corresponding to the combined single-unit and multi-unit estimates must lie between the separate estimates. Those symbols which

represent ratio estimates whose differences from one are greater than 2 standard errors are enclosed in a triangle.

In general these charts show that the multi-units' reported data consistently exceeds the administrative data across all variables, trade areas, and all but the most stringent outlier adjustment scheme. The ratios for single units display basically the same behavior although the lines representing single units occasionally do fall below one. Also, multi-unit ratios tend to be above single-unit ratios in all but a few cases. Although the value of the ratios differs widely, the ranges over which all twelve charts are drawn require values from .90 to as high as 2.3 (i.e. 230%) and in 8 of the 12 charts the minimum value is 1.00 (i.e. no ratios were less than one), reinforcing the impression that the reported data exceeds the administrative data under most of the conditions presented.

Two patterns emerged from the use of these multiple outlier adjustments. The first is a L-shaped pattern observed for all variables in both wholesale and retail trade areas. This pattern represents a sharp reduction in the ratio estimate from the unadjusted level to the 7.5 adjustment level and basically stable estimates over all levels of adjustment. Combining this observation with the variance reduction achieved by this adjustment points toward using this set of estimates as the set upon which to focus attention. This pattern does not apply to the variables of the service industries. Here the graphs show a steady decline from left to right with a sharp turn appearing at the most stringent level of outlier adjustment. There is less stability over the range of outlier adjustment suggesting that the services data are subject to fewer large outliers than wholesale and retail. Attention should again be focused at the 7.5 adjustment level as the variances for these estimates are greatly reduced from the unadjusted levels.

Using the "conservative" estimate and the 7.5 outlier adjustment factor, the following table summarizes results at the trade area level for each variable. The standard error of the ratio estimator appears in parentheses.

Ratio: "Reported"

Data to Adminis-
trative Data

	Wholesale	Retail	Services
Sales/Receipts	1.038 (.0355)	1.053* (.0262)	1.113** (.0296)
Annual Payroll	1.103** (.0315)	1.041* (.0192)	1.068* (.0278)
IQ Payroll	1.134** (.0343)	1.054** (.0204)	1.071* (.0287)
IQ Employment	1.181** (.0358)	1.145** (.0270)	1.252** (.0361)

*Significant at the 5% level

**Significant at the 1% level

All of the variables display "reported" data exceeding administrative data, but IQ employment stands out as being markedly higher than the other variables. Also the IQ payroll estimates are slightly higher than the annual payroll estimates over all trade areas. The ratio for reported services receipts versus administrative receipts, 11.3%, is nearly triple than that of wholesale sales and double that of retail sales.

Below is a short discussion of each of the twelve charts. (Pages 21-32).

Wholesale Trade - Sales

Only four points show significance (the lowest of any chart). Also these points represent multi-units with no outlier adjustment and single units with the extreme outlier adjustment (2.5). These points also occur at the highest (multi-units) and lowest (single units) values for the ratio estimators. There is no definite conclusion to be drawn from these data.

Wholesale Trade - Annual Payroll

Here the multi-unit points are significant for all levels of outlier adjustment (except no adjustment), while the single unit data are not significant at any point. The points corresponding to the trade area as a whole for this variable are significant except for the rightmost point. It appears that the reported annual payroll exceeds administrative annual payroll by a factor in the area of 10%.

Wholesale Trade - IQ Payroll

A similar picture as annual payroll above except that the single units are significant at the 7.5 outlier level. The multi-units' ratio is 22% while for the entire trade area, the level is 13%.

Wholesale Trade - IQ Employment

Only two of the points (multi-unit with no outlier adjustment) are not significant. One of these points corresponds to the highest ratio completed 2.26. However, the consistency of the estimates with outlier adjustment shows that the reported data exceed the administrative data in the area of 28% for multi-units, 13% for single units and 18% overall.

Retail Trade - Sales

Again the most consistent pattern belongs to the multi-unit estimates with the single units and combined units also showing significance but not as strongly. The single unit picture is clouded in that significant estimates are obtained only at the extremes (i.e., no outlier adjustment and with the outlier factor equal to 2.5). The multi-unit ratio estimates are in the area of 12% while over all units the estimate is 5%.

Retail Trade - Annual Payroll

The data here suggest that the reported data exceed the administrative data by about 4% for both types of units in retail. However, the pattern for the ratio estimators being significant is not strong for this chart.

Retail Trade - IQ Payroll

Similar results apply here as applied to the annual payroll data for retail trade, however the level of difference observed appears to be slightly higher than the 4% observed for annual payroll.

Retail Trade - IQ Employment

This chart has each of the thirty points charted as significant ranging from a high estimate of 1.70 to a low of 1.045. A conservative estimate for the reported data exceeding the administrative data is in the area of 15% for all types of units.

Service Industries - Receipts

A strong pattern of significant estimates exists over all types of units with the multi-units showing a higher range of estimates than the single units. The differences appear slightly over 11% for the entire trade area.

Service Industries - Annual Payroll

Similar results appear here as for the retail trade area with the combined units only showing significance at near the 7% level.

Service Industries - IQ Payroll

This variable follows the pattern of annual payroll for services. The common phenomenon of the multi-units being highly significant, the single units not being significant and with the combined units following the multi-units is quite clear on this chart. As previously observed in both wholesale and retail

trade, the level of the ratio estimator is higher for IQ payroll than for annual payroll.

Service Industries - IQ Employment

As with retail trade, all points graphed appear within a triangle as significant. The level of reported over administrative here appears to be higher than retail trade occurring at the 25% level.

It was mentioned previously that the tabulated data and the "prior" administrative were equal most of the time. The following table shows the number of cases where the data were equal. The base for these numbers is the original sample plus all of the supplements since data exist for almost all of the cases. The only cases omitted were those where a match was not able to be made to the tabulation files or a particular variable had a zero as its value.

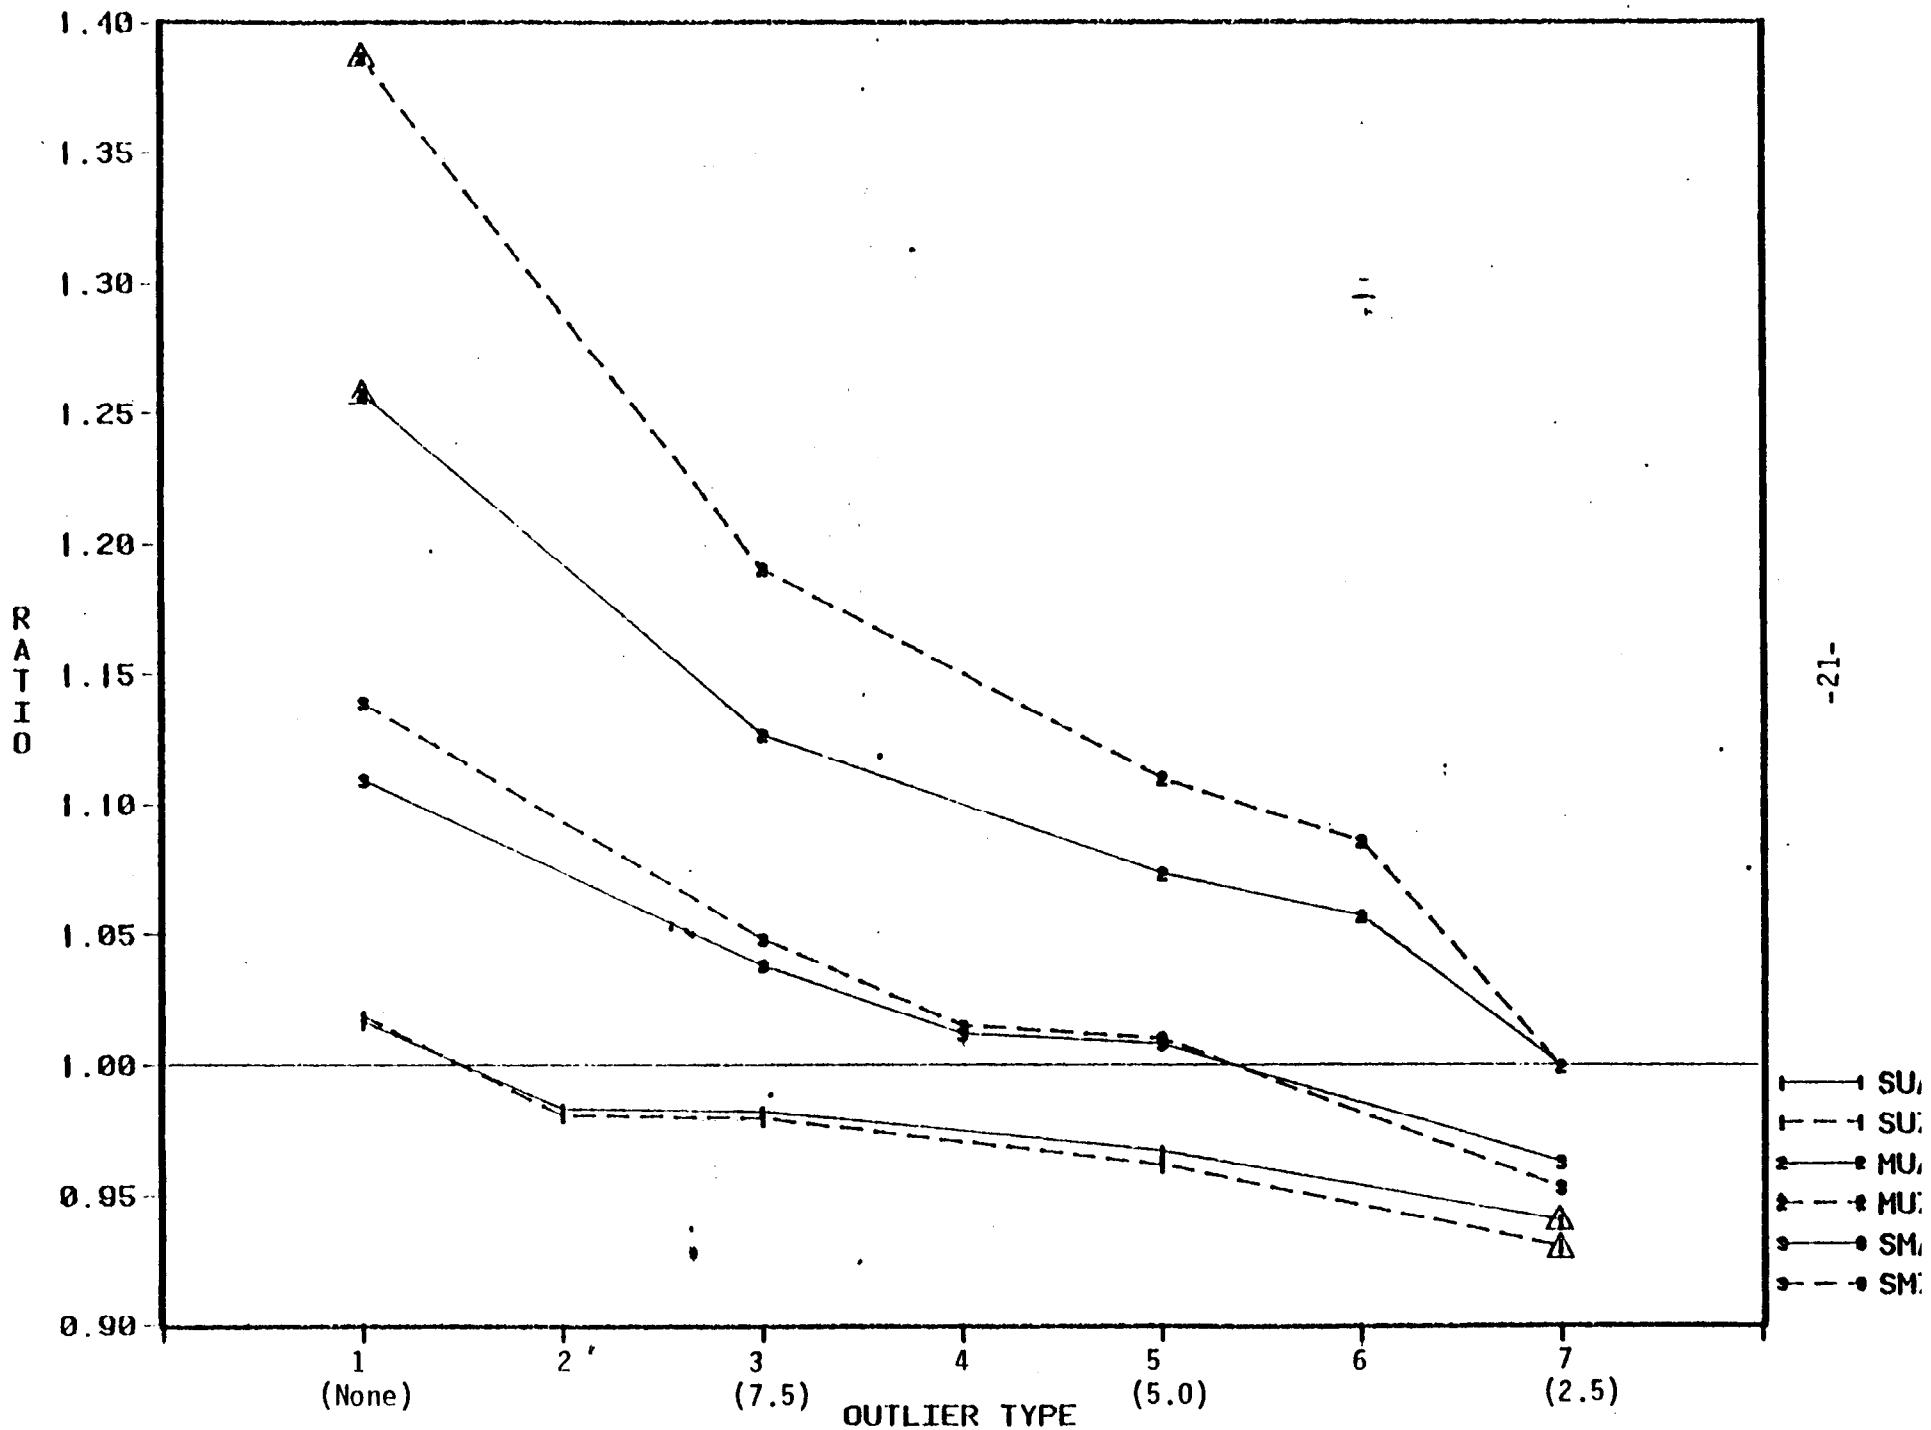

of sample cases where the administrative value exactly equaled
the tabulated value

	TOT	Sales/Receipts	Annual Payroll	IQ Payroll	IQ Employment
WHL-SU	628	604/623	622/623	619/621	619/619
WHL-MU	451	408/442	441/442	441/442	440/442
WHL-TOTAL	1079	1012/1065	1063/1065	1060/1063	1059/1061
RET-SU	1623	1540/1571	1561/1570	1530/1539	1506/1518
RET-MU	1007	872/944	920/944	915/939	909/937
RET-TOTAL	2630	2412/2515	2481/2514	2445/2478	2415/2455
SERV-SU	1761	1714/1738	1731/1738	1687/1693	1655/1664
SERV-MU	557	540/551	542/551	541/549	543/549
SERV-TOTAL	2318	2254/2289	2273/2289	2228/2242	2198/2213

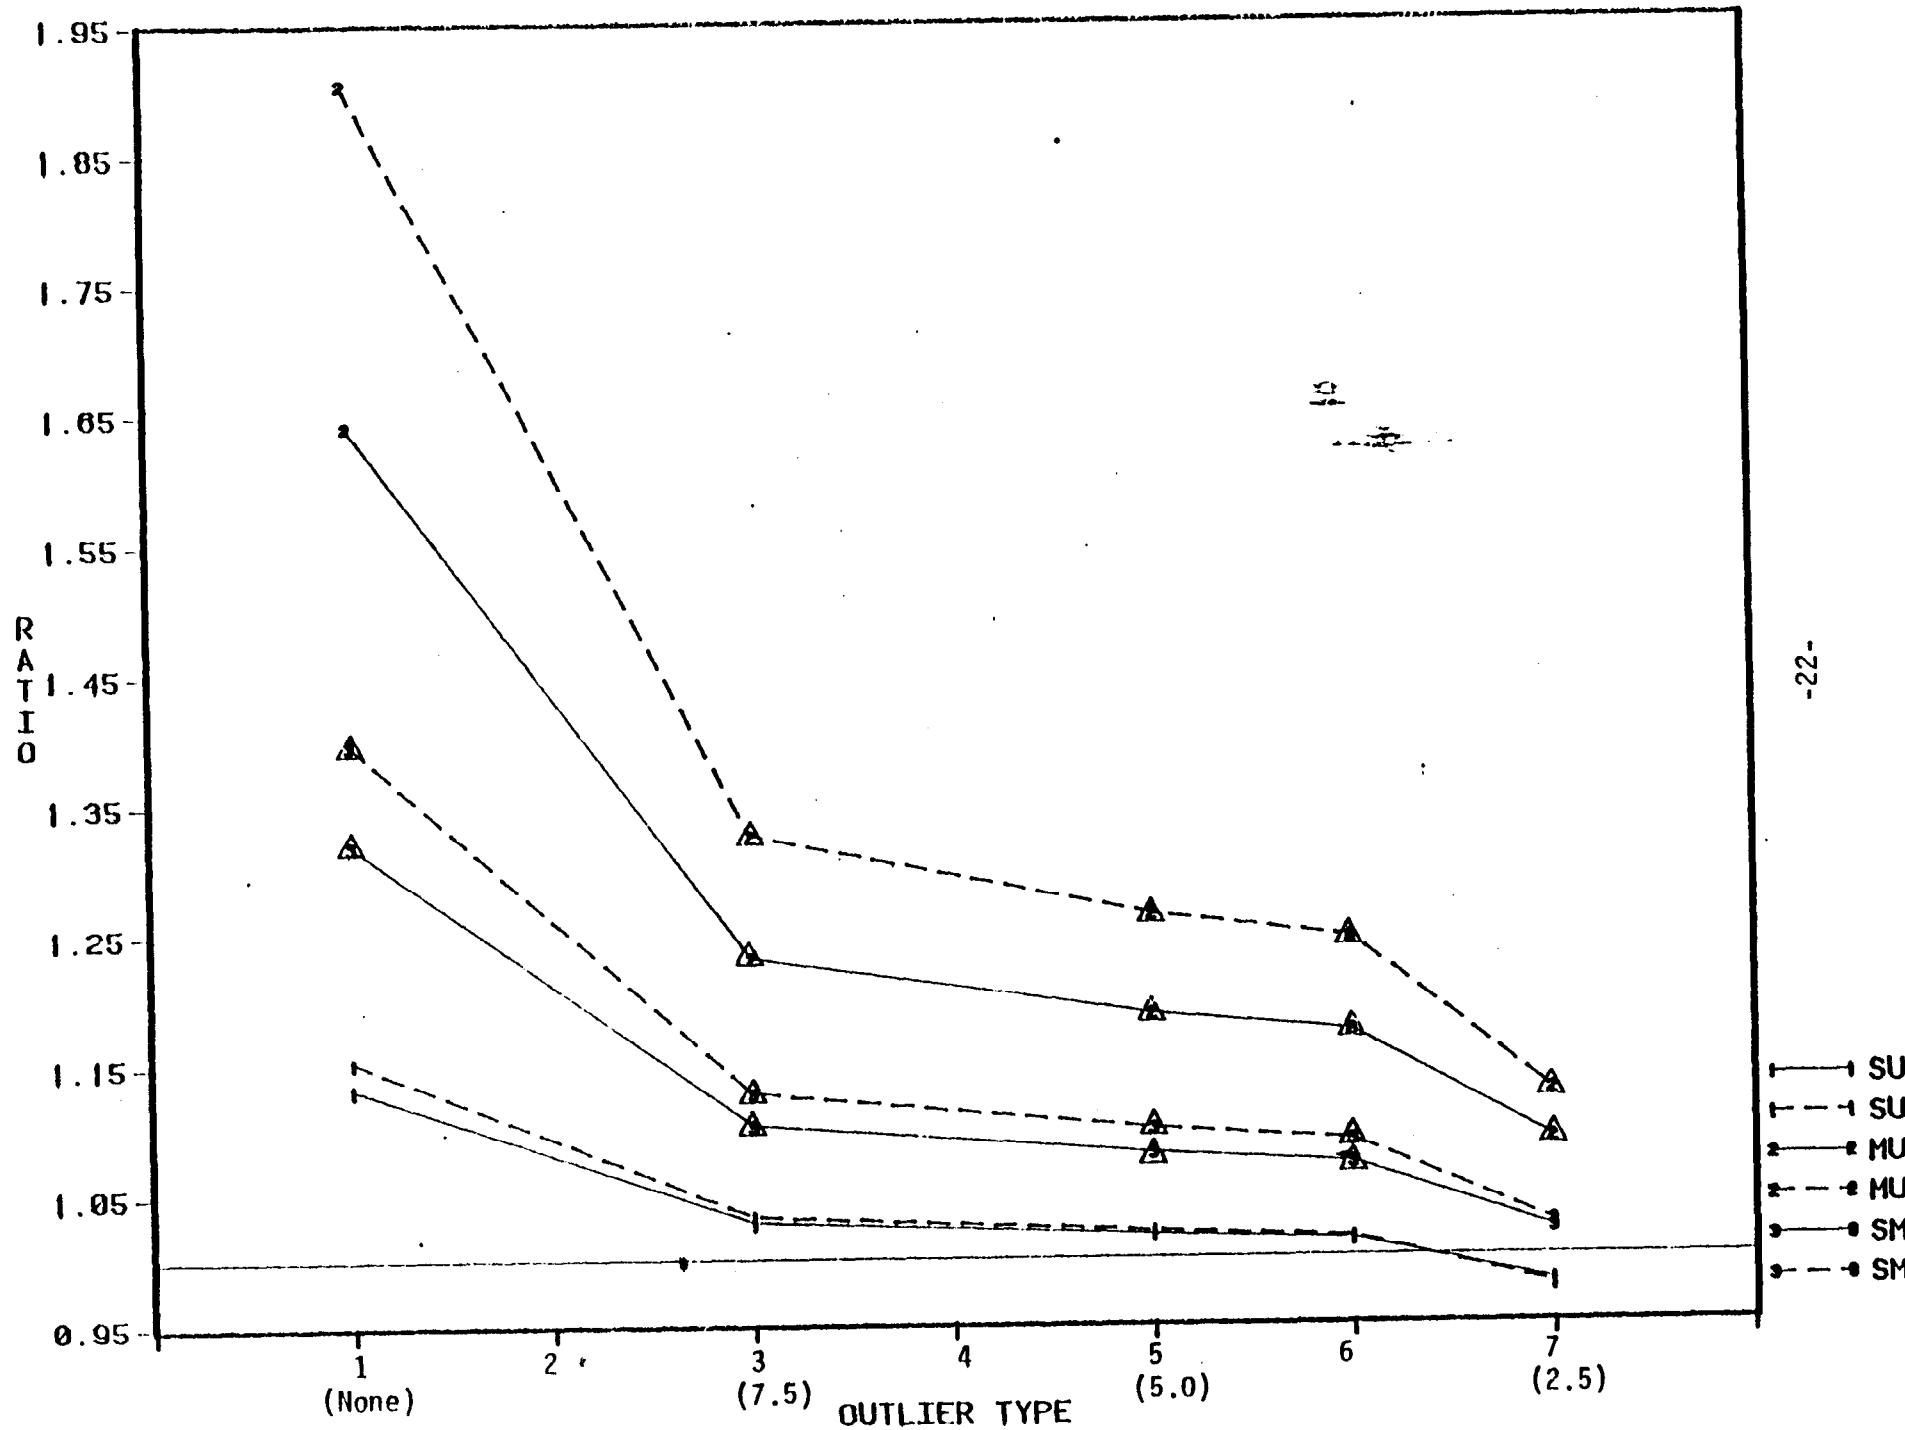

Both retail trade and service industries experienced a larger loss of units from the administrative file to the tabulation file than did wholesale trade. However, even for these two trade areas the loss is less than 5%. Also, first quarter employment is affected by missing data more than the

other variables. The sales/receipts variable is more likely to be affected than the other variables if the data values are not exactly equal. A closer examination of the data reveals that the most common case was the sales/receipts value to be changed (either by a computer edit or an analyst) while the other values were unchanged.

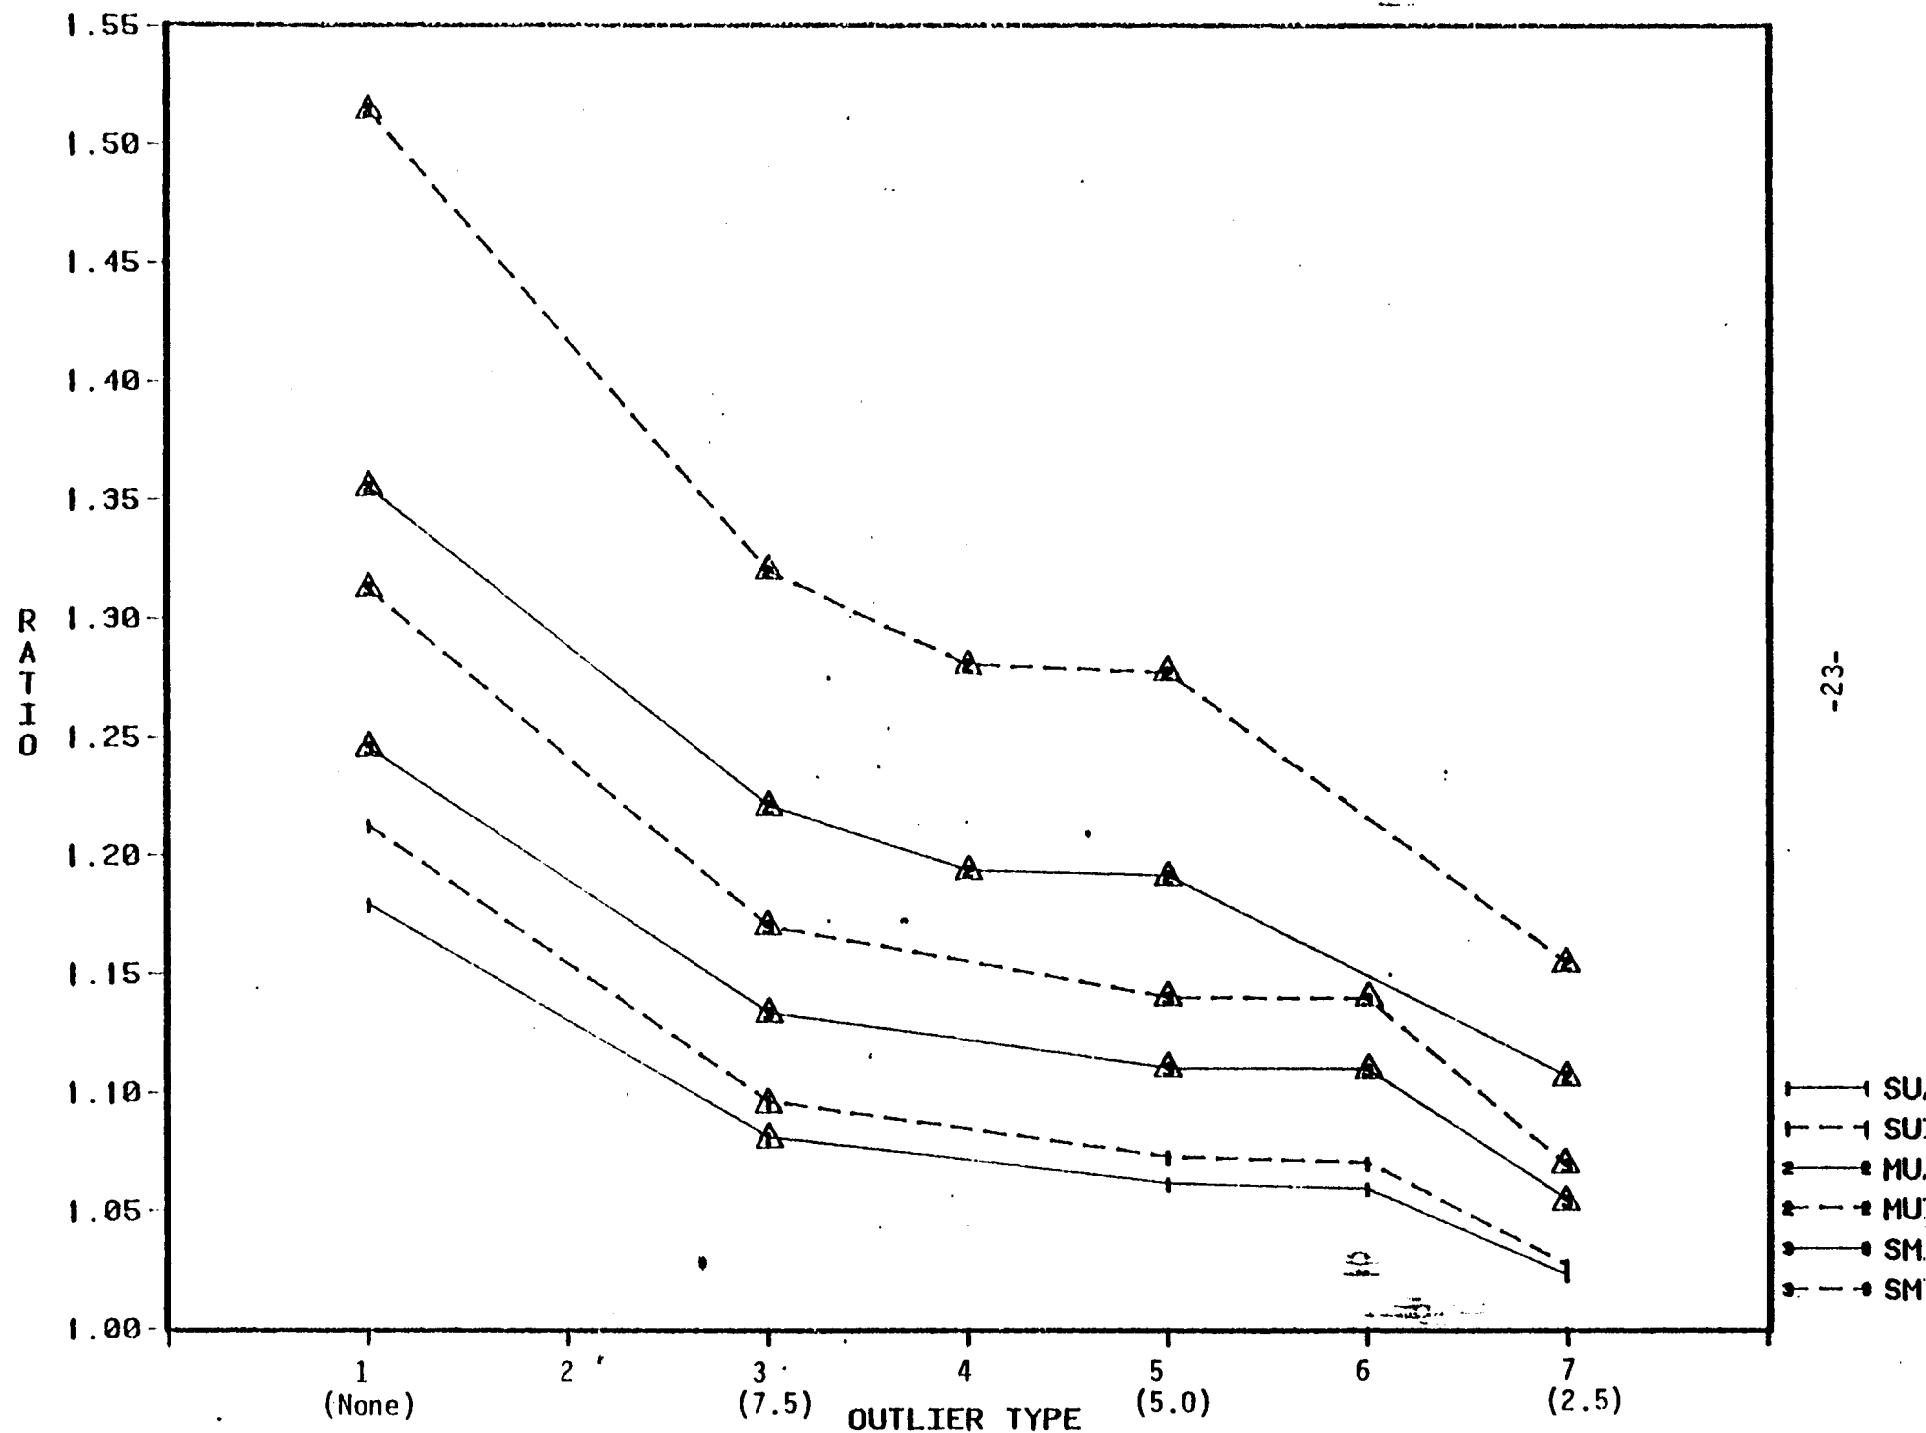

WHOLESALE TRADE - SALES

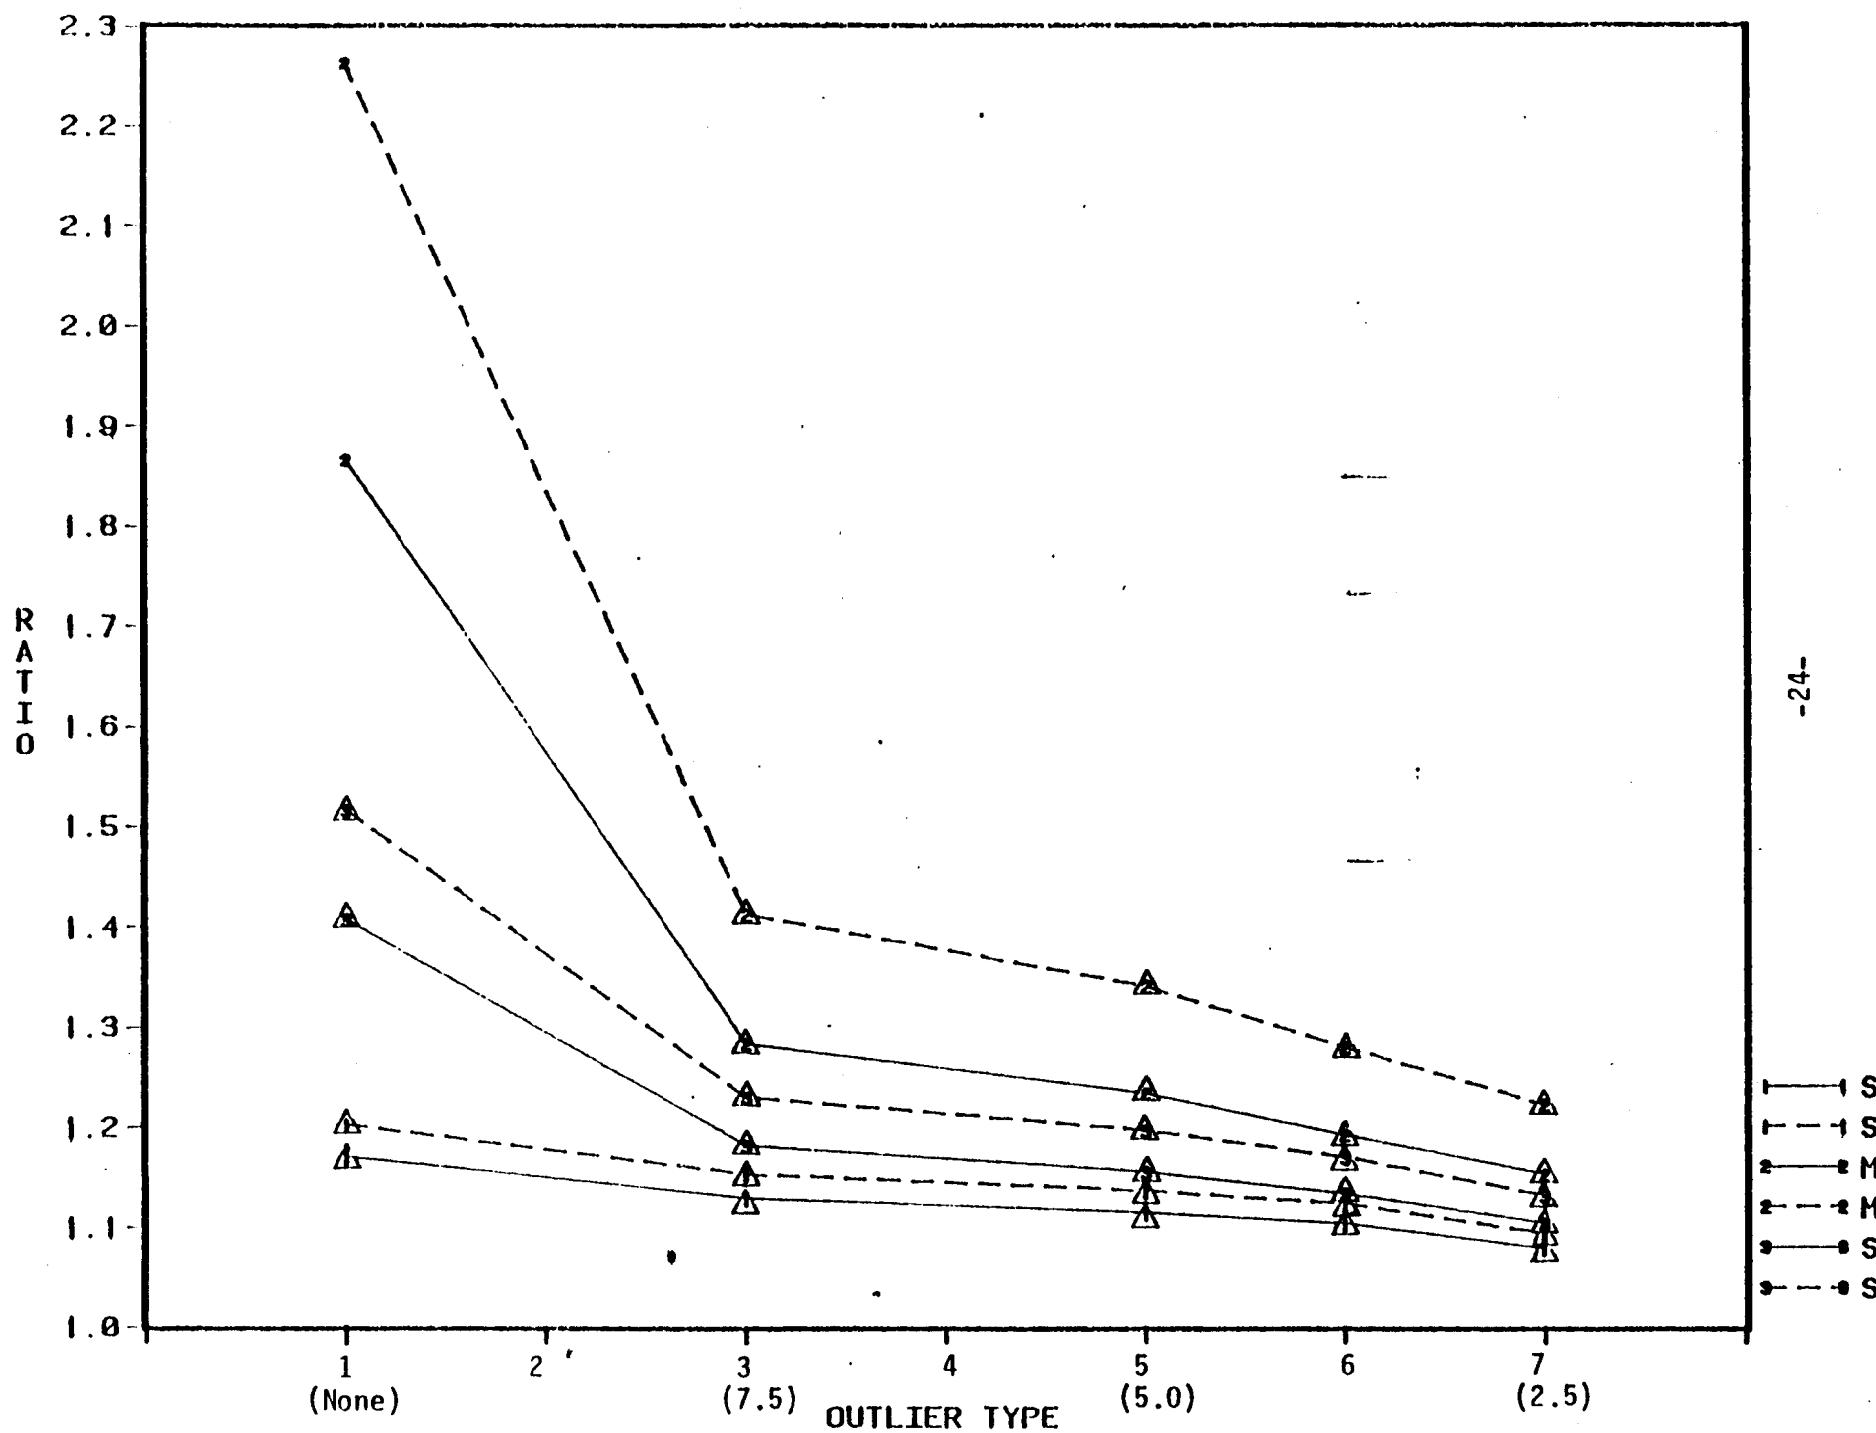

WHOLESALE TRADE - ANNUAL PAYROLL

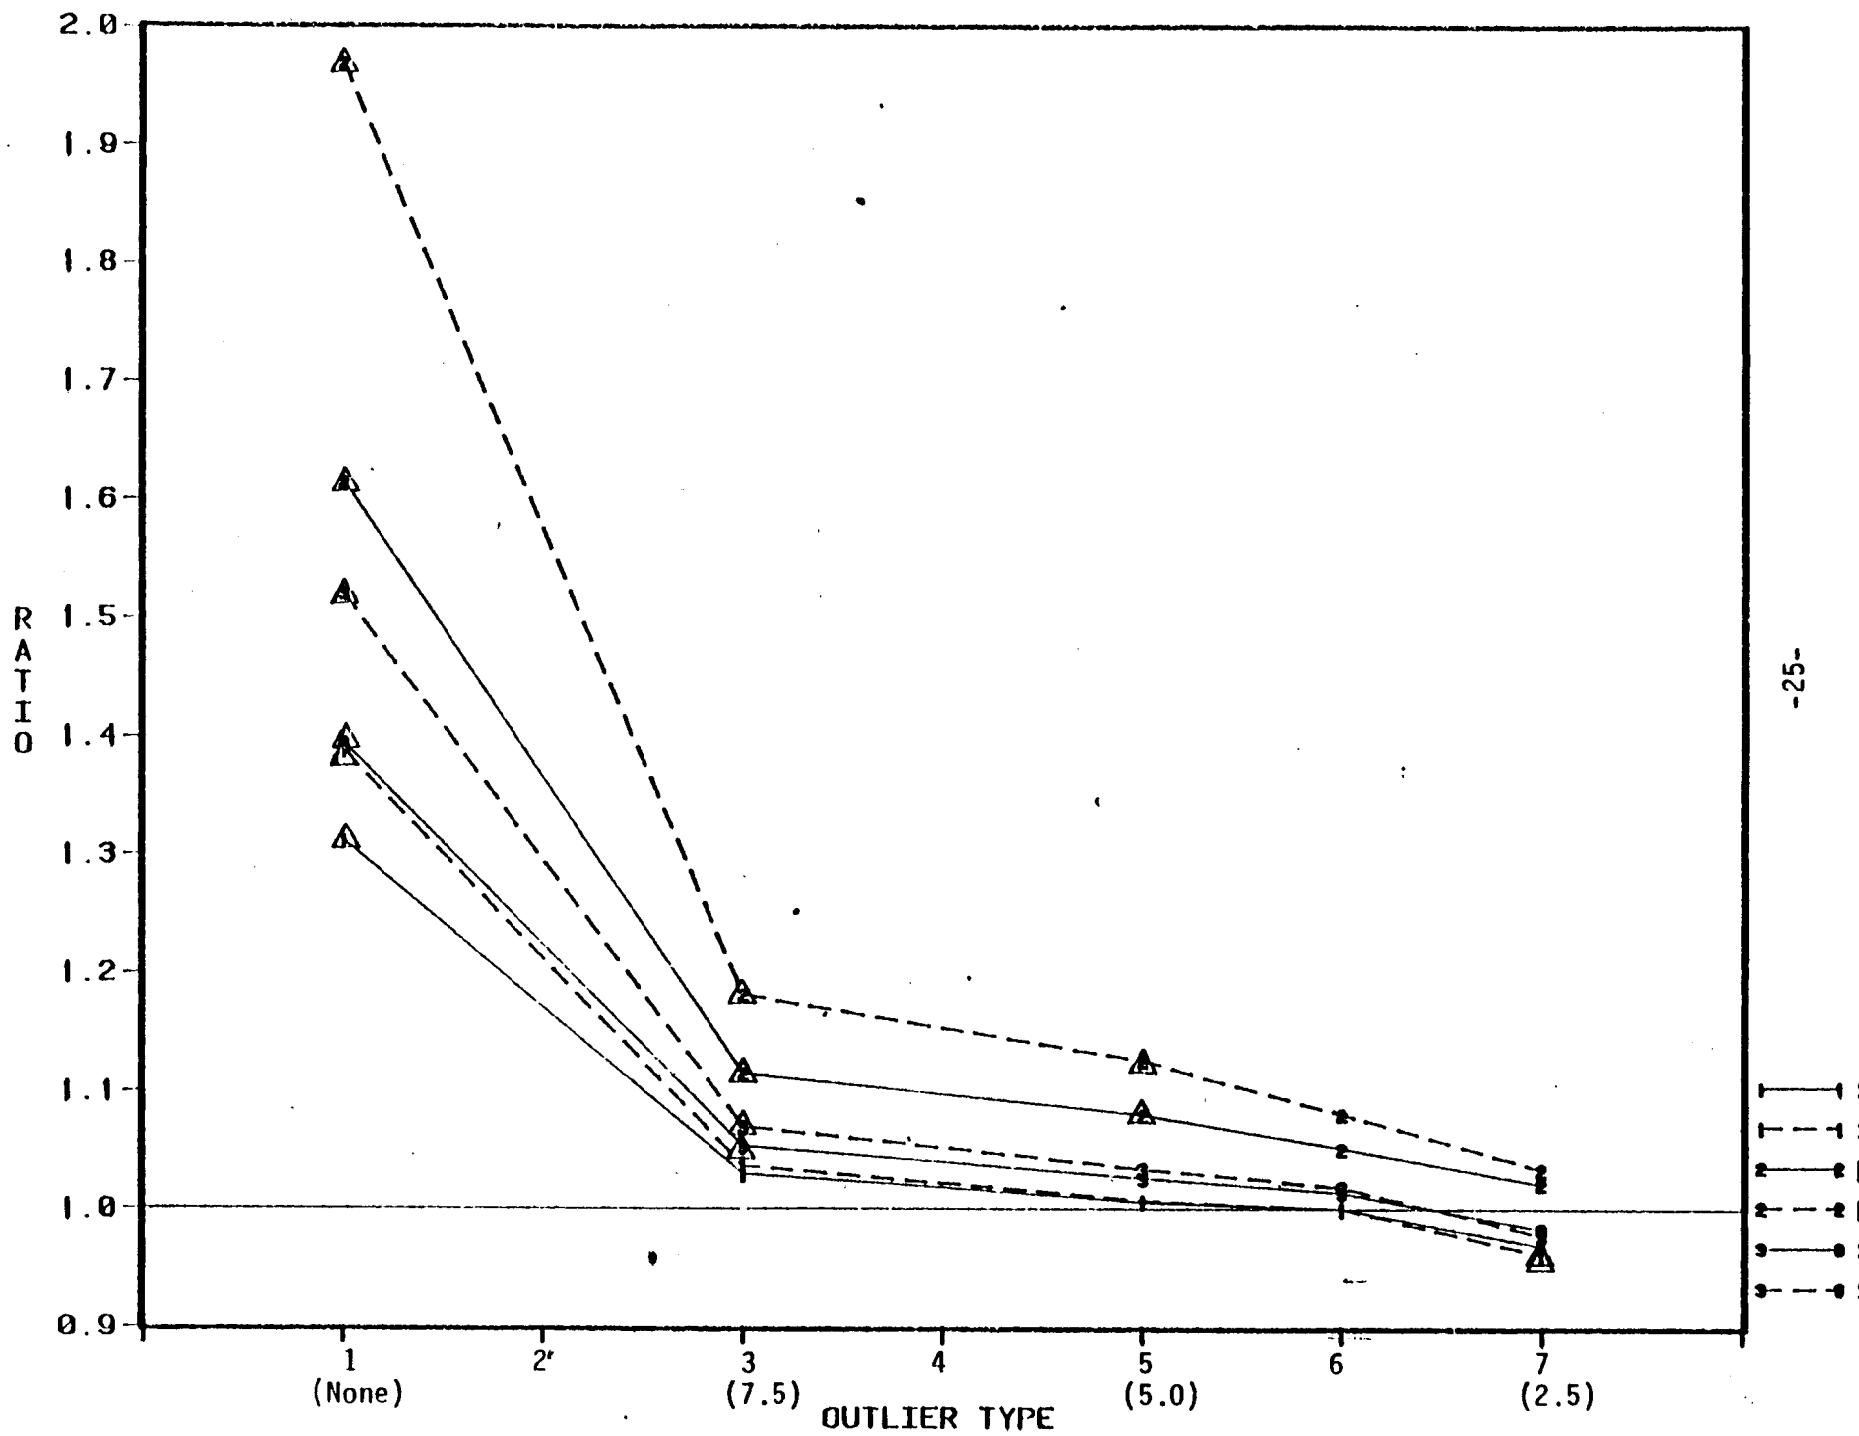

WHOLESALE TRADE - IQ PAYROLL

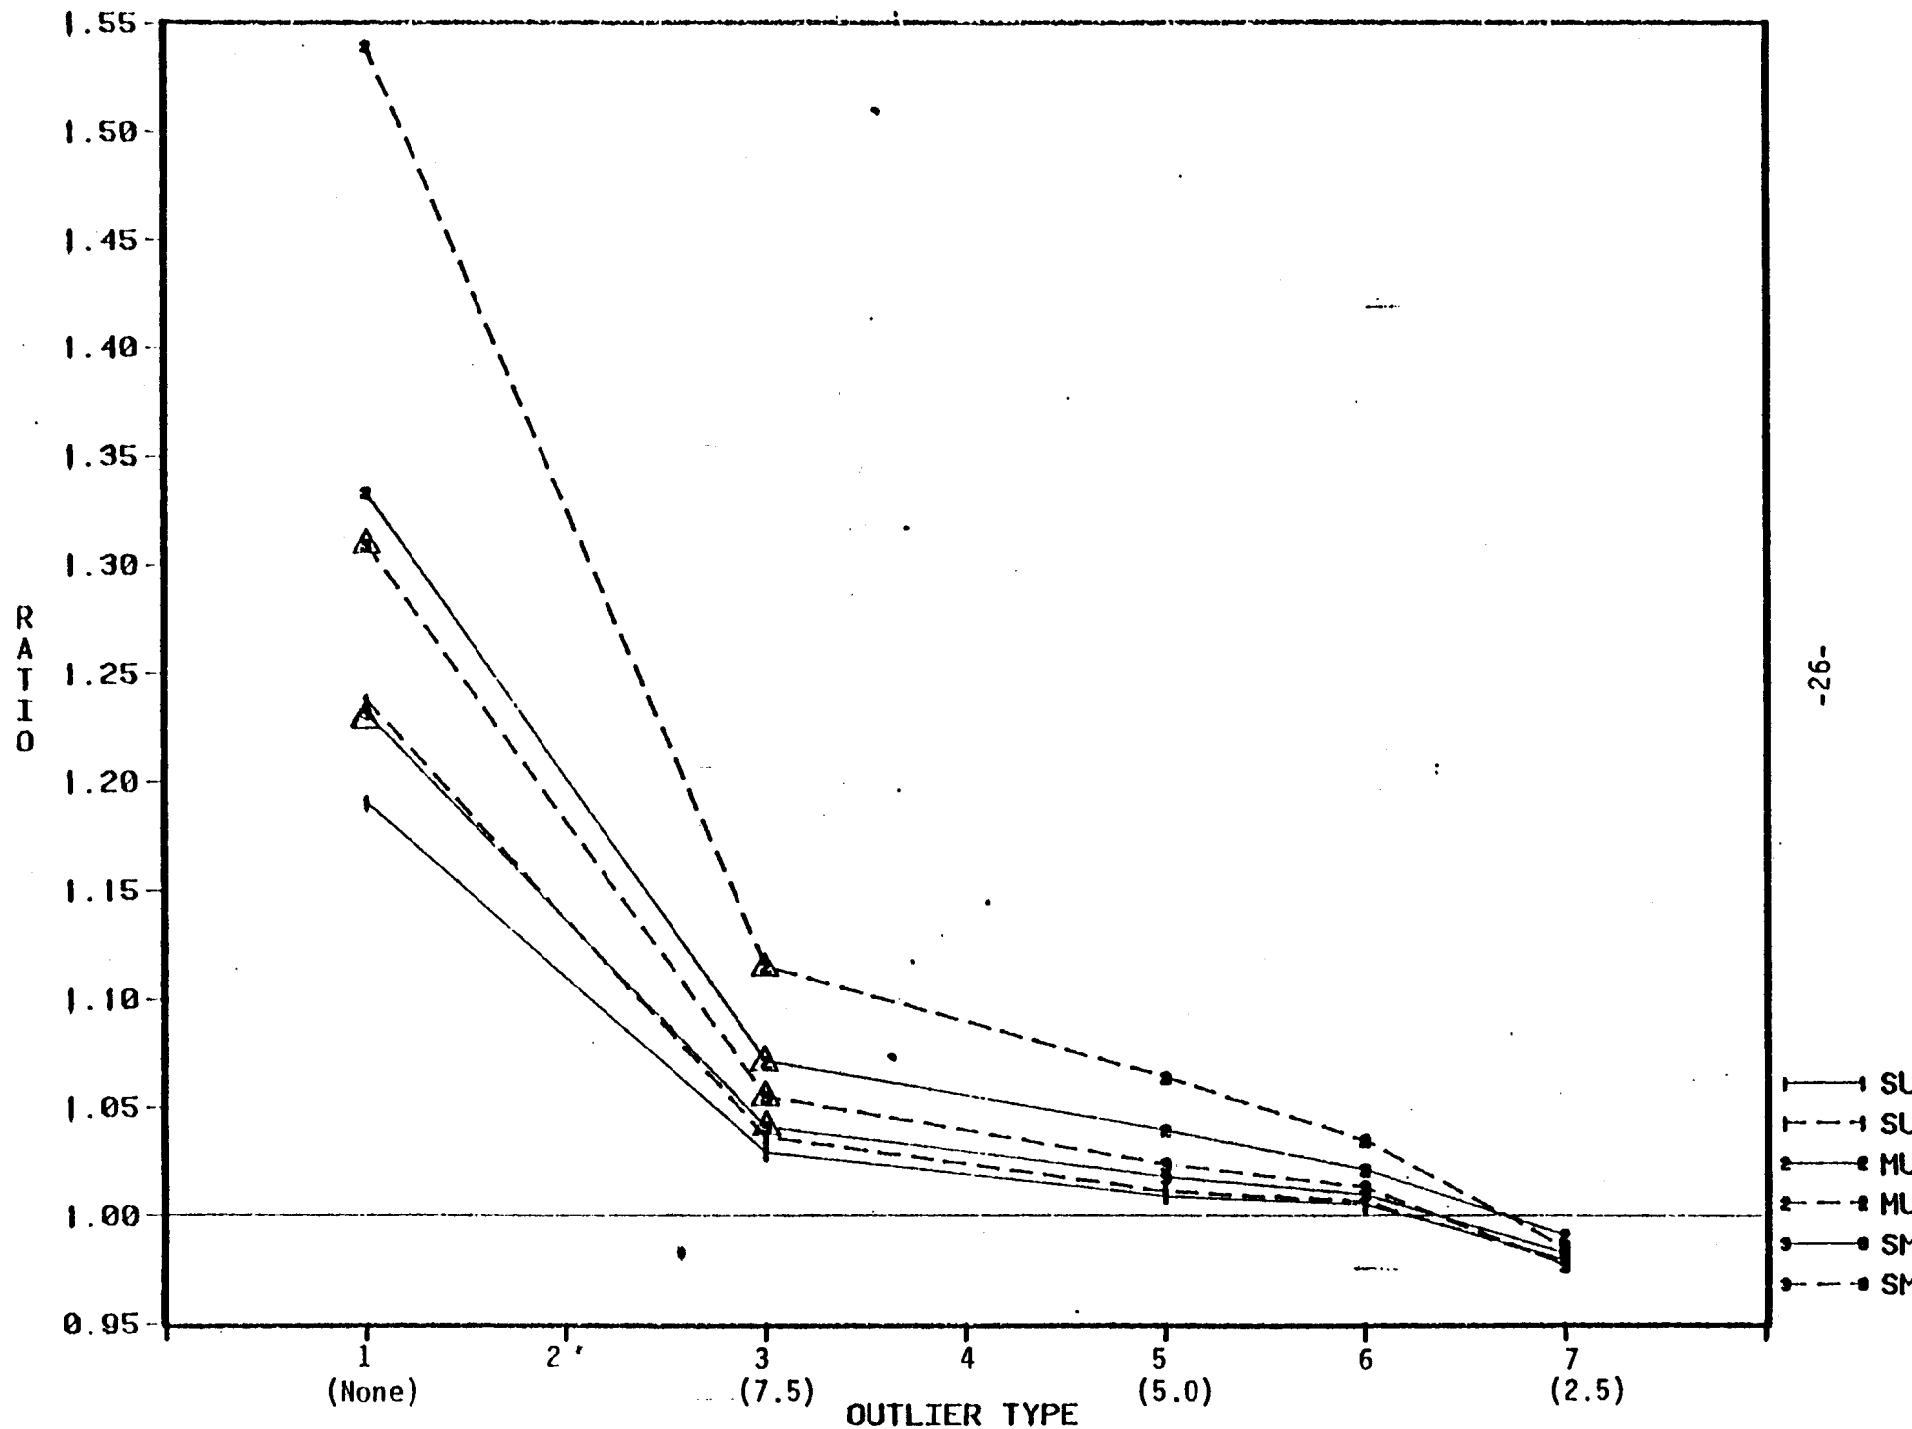

WHOLESALE TRADE - IQ EMPLOYMENT

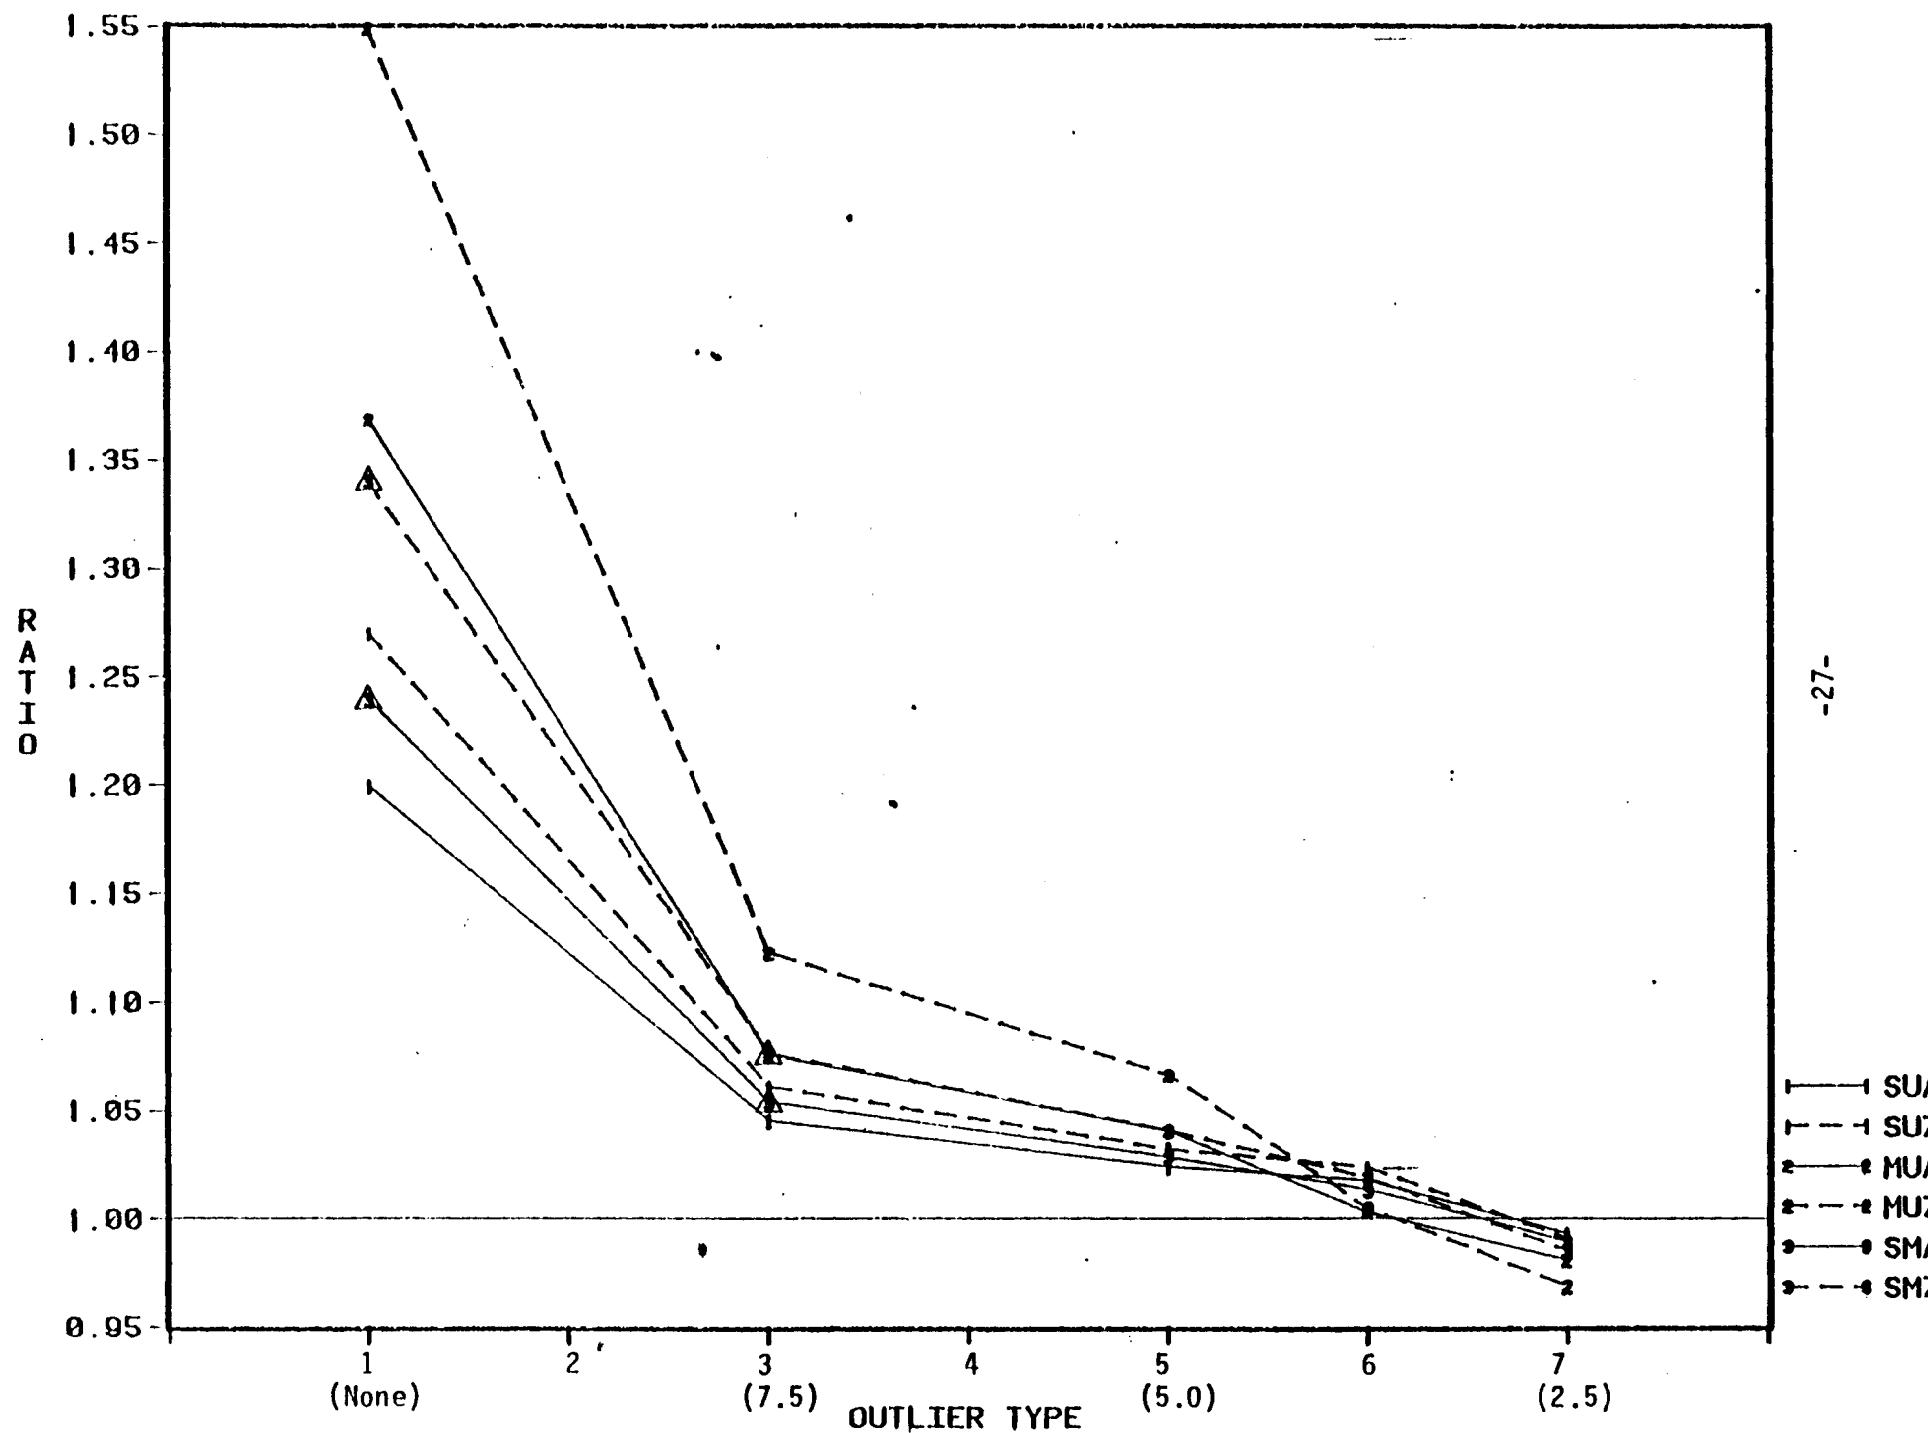

RETAIL TRADE - SALES

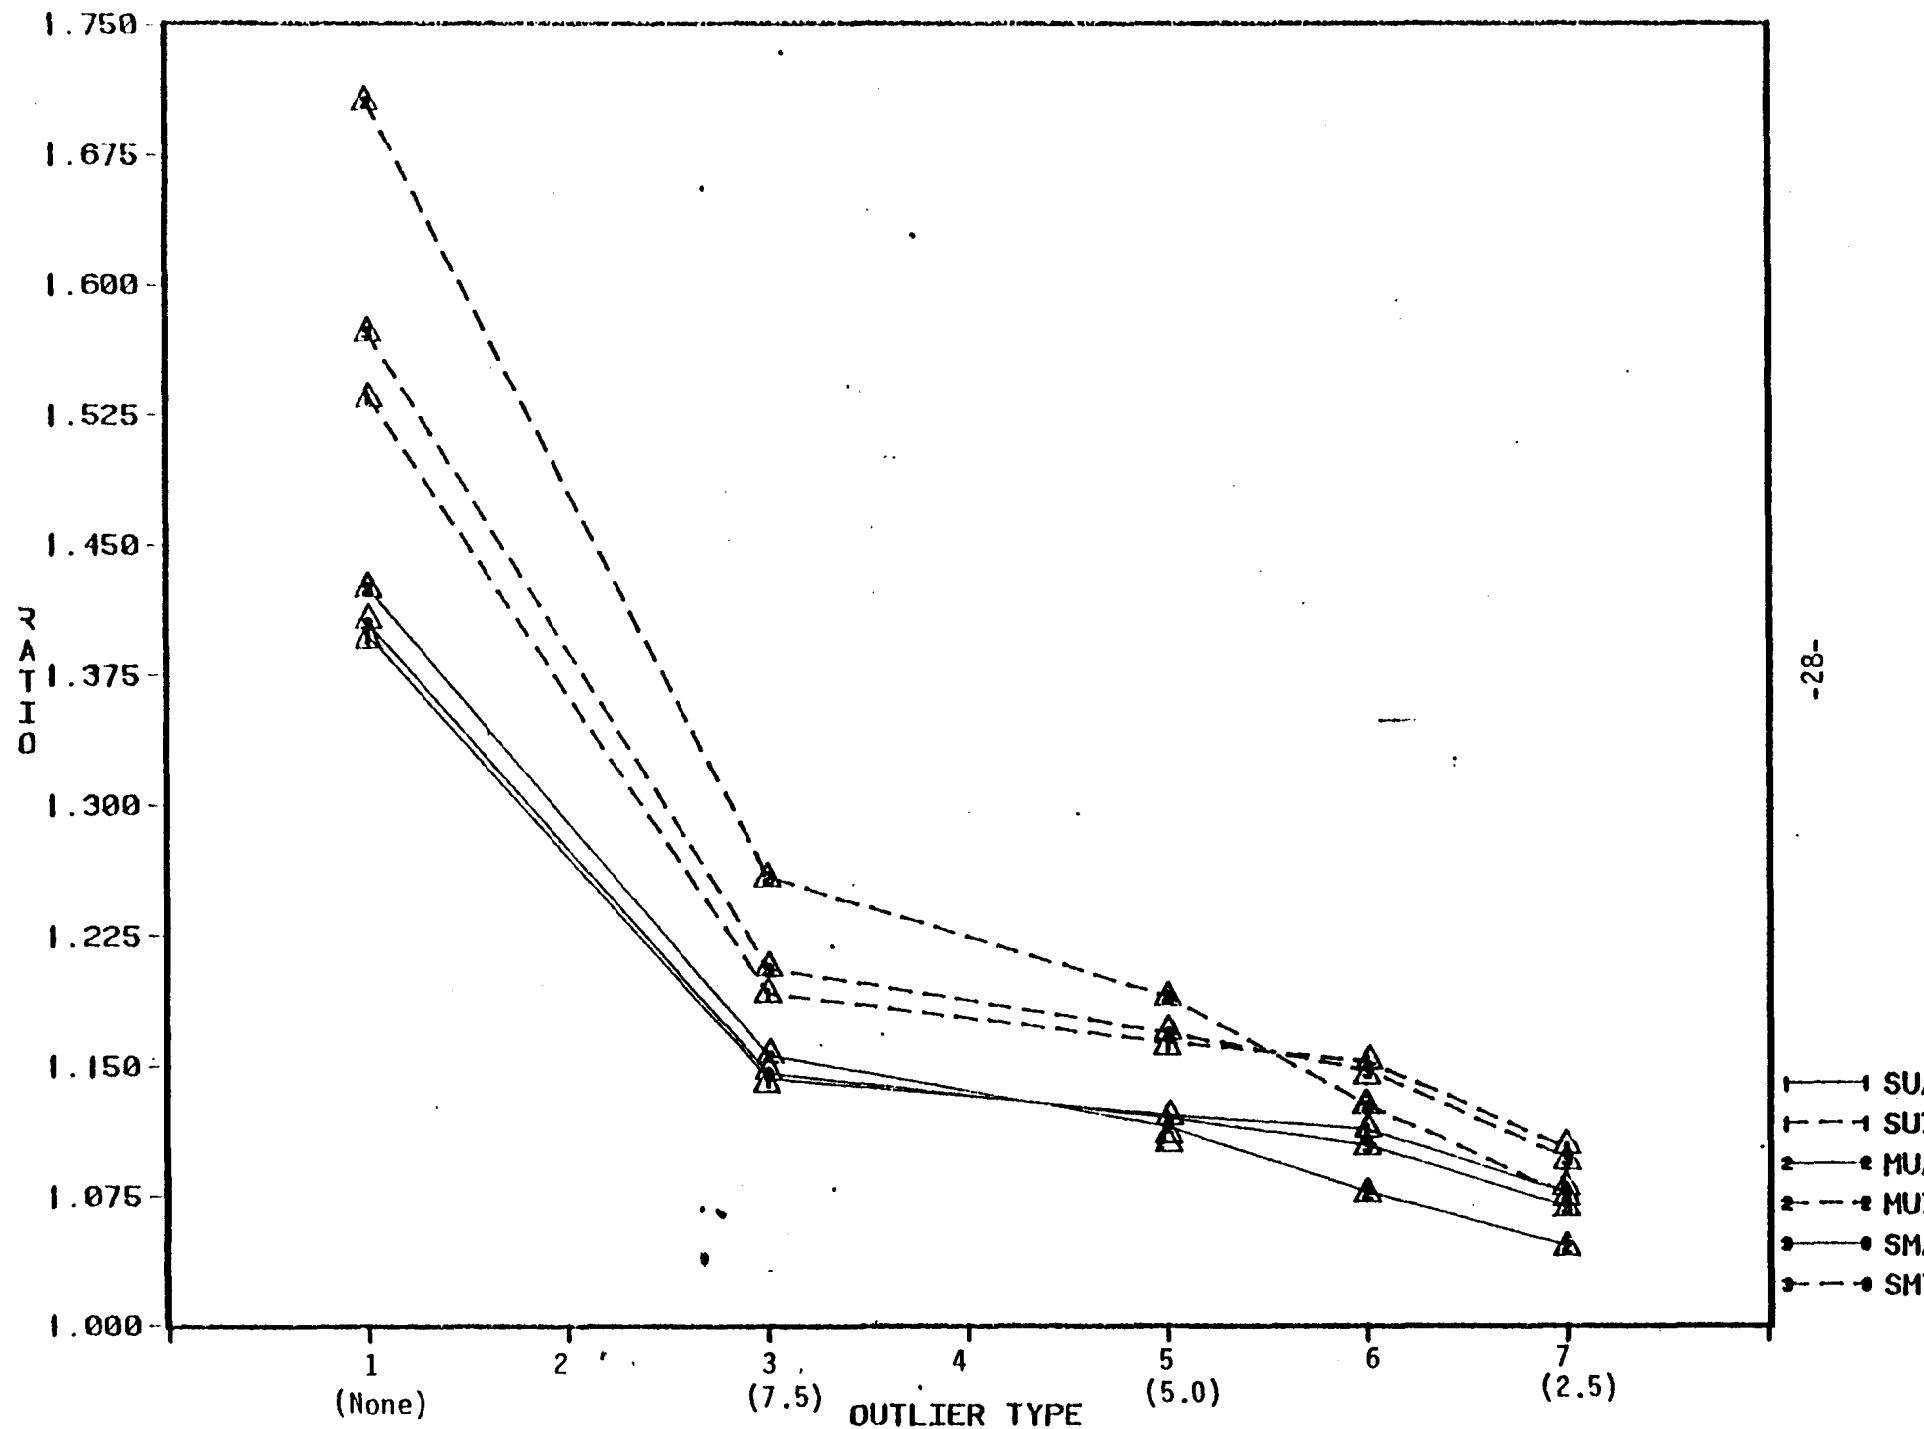

RETAIL TRADE - ANNUAL PAYROLL

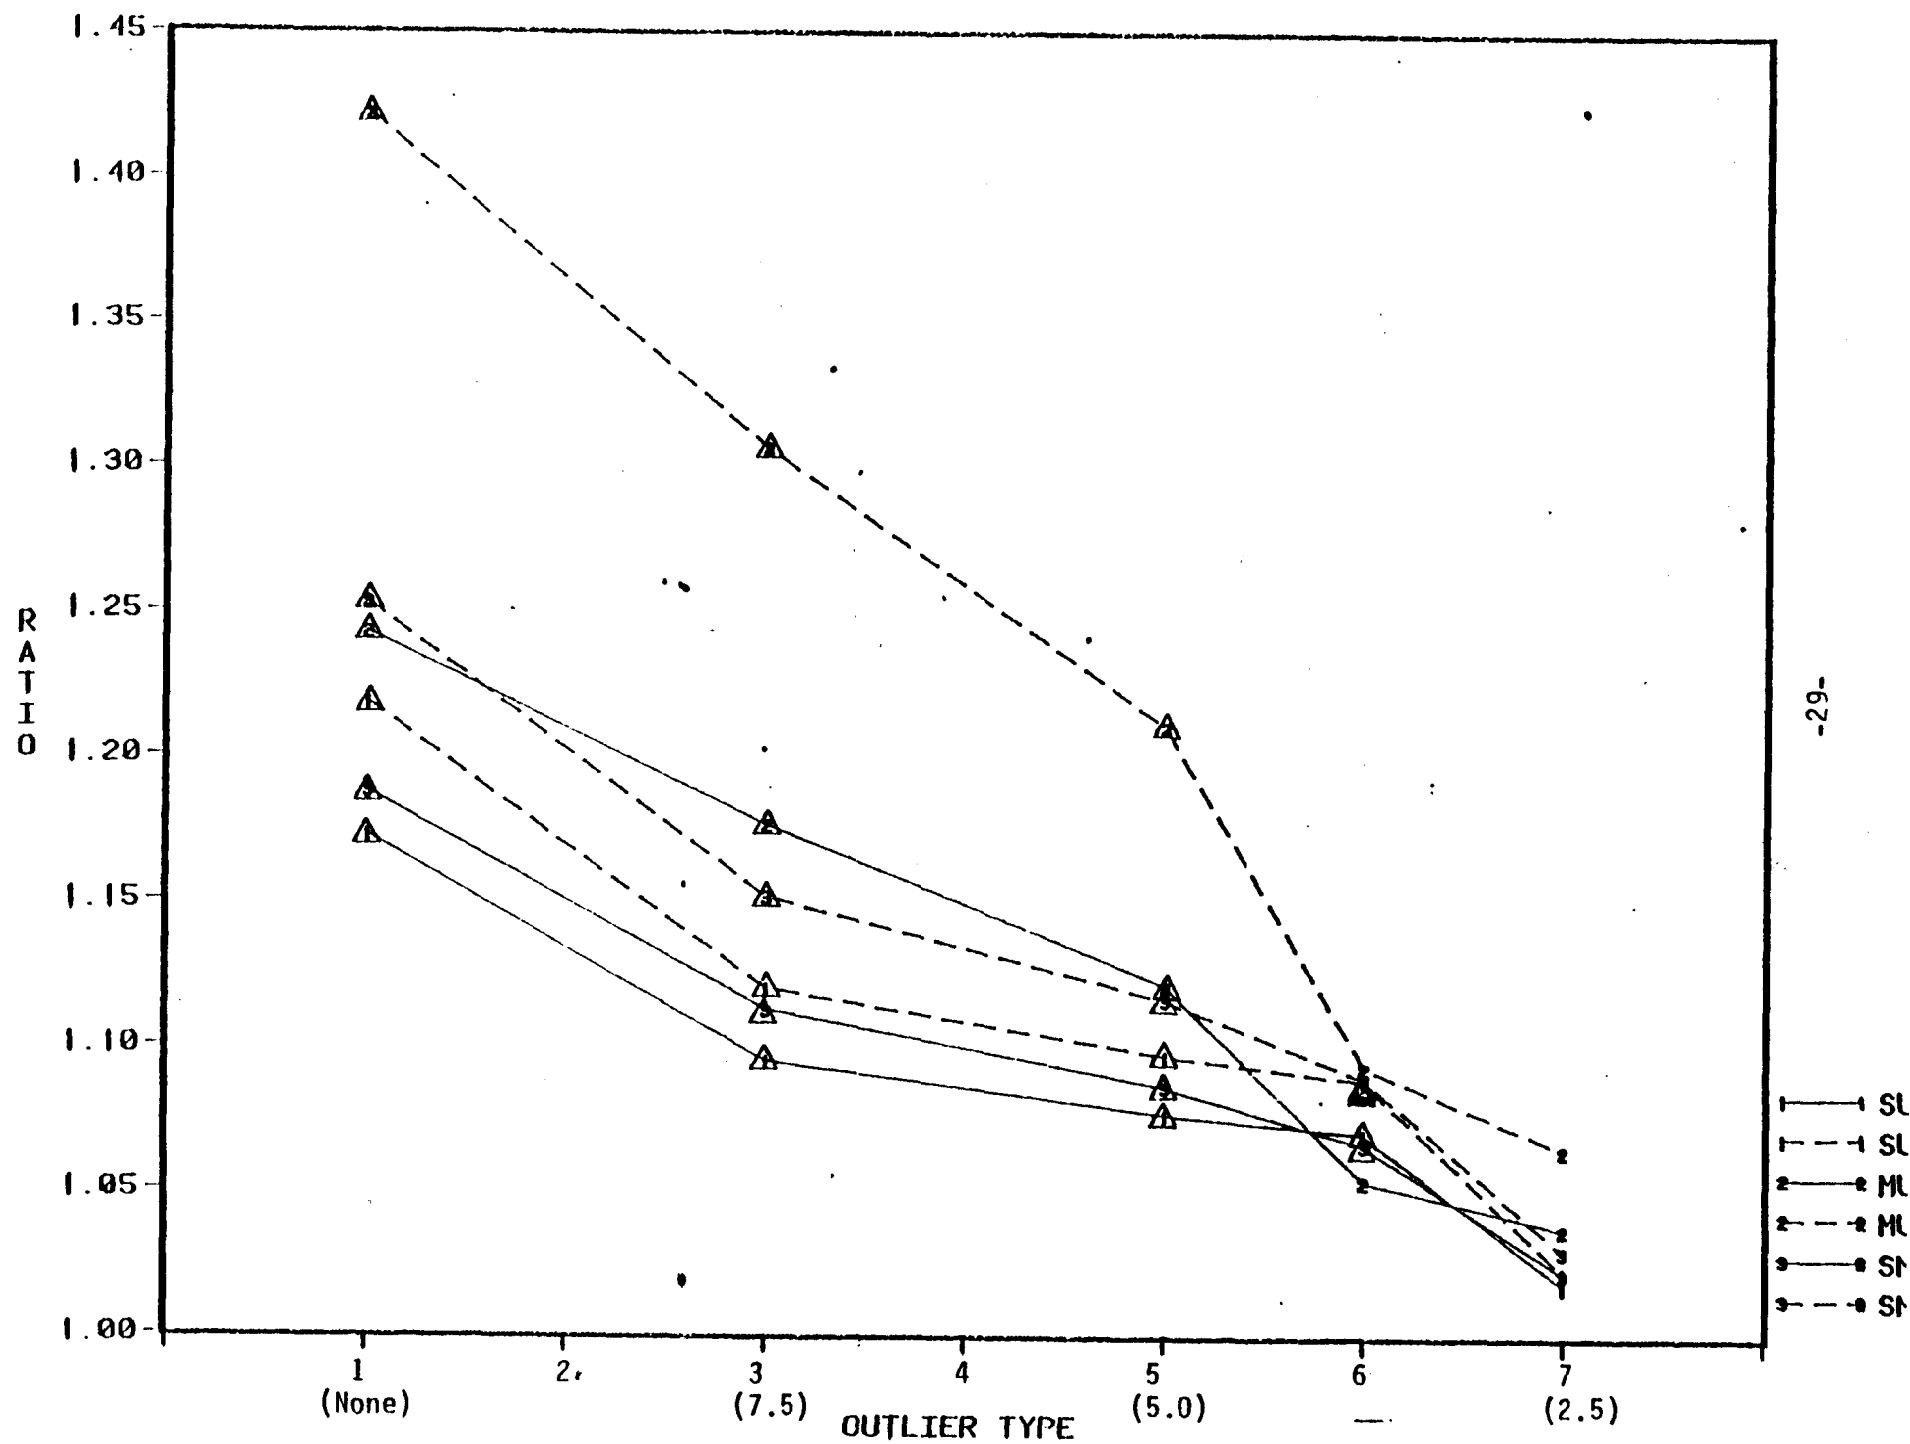

RETAIL TRADE - IQ PAYROLL

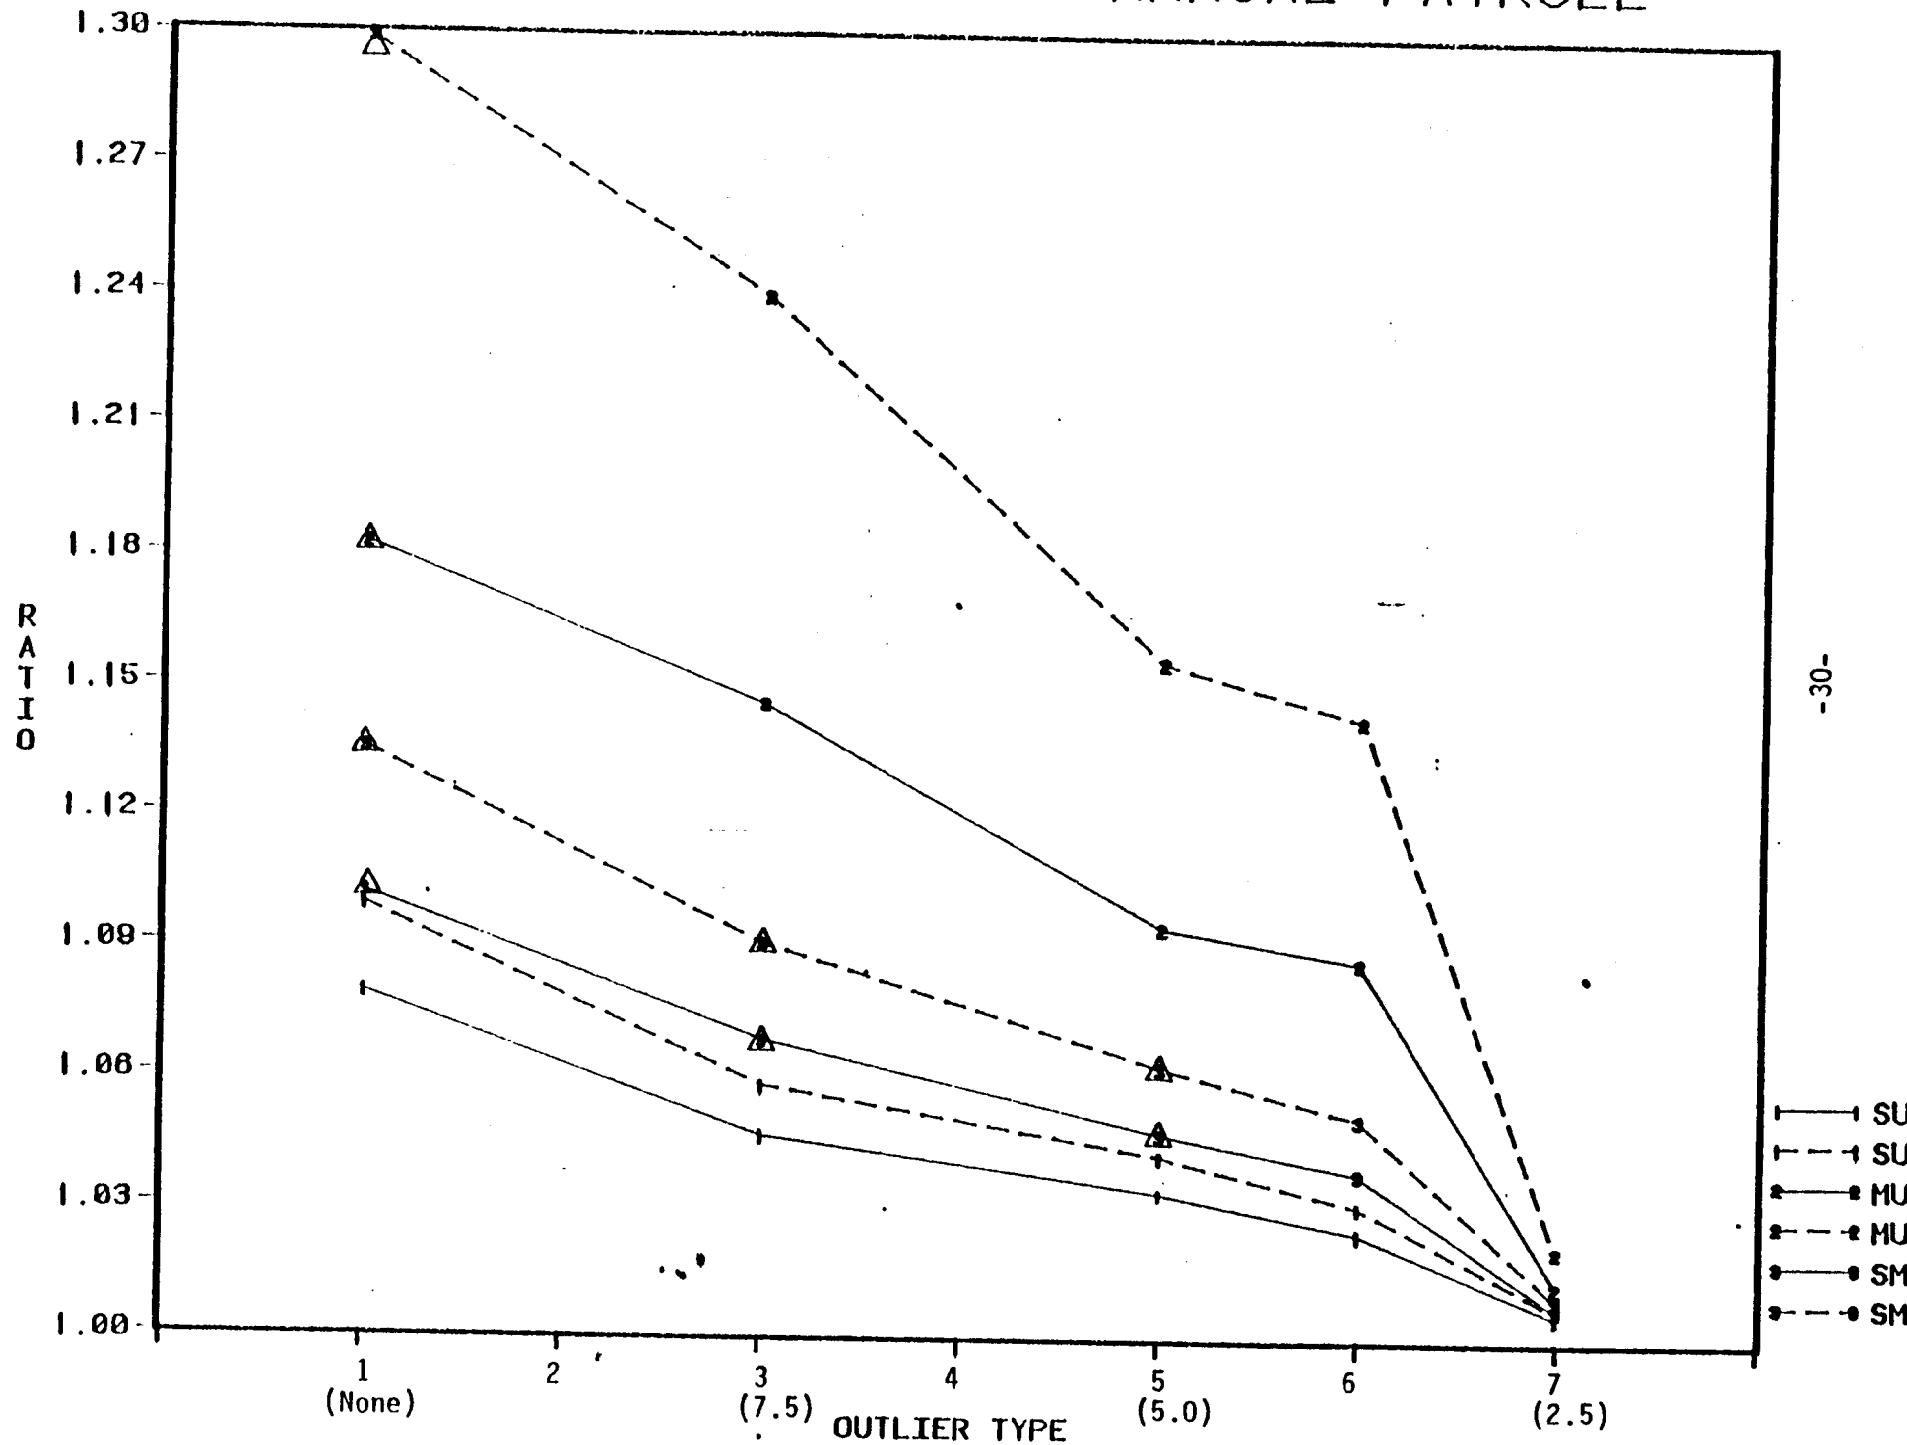

RETAIL TRADE - IQ EMPLOYMENT

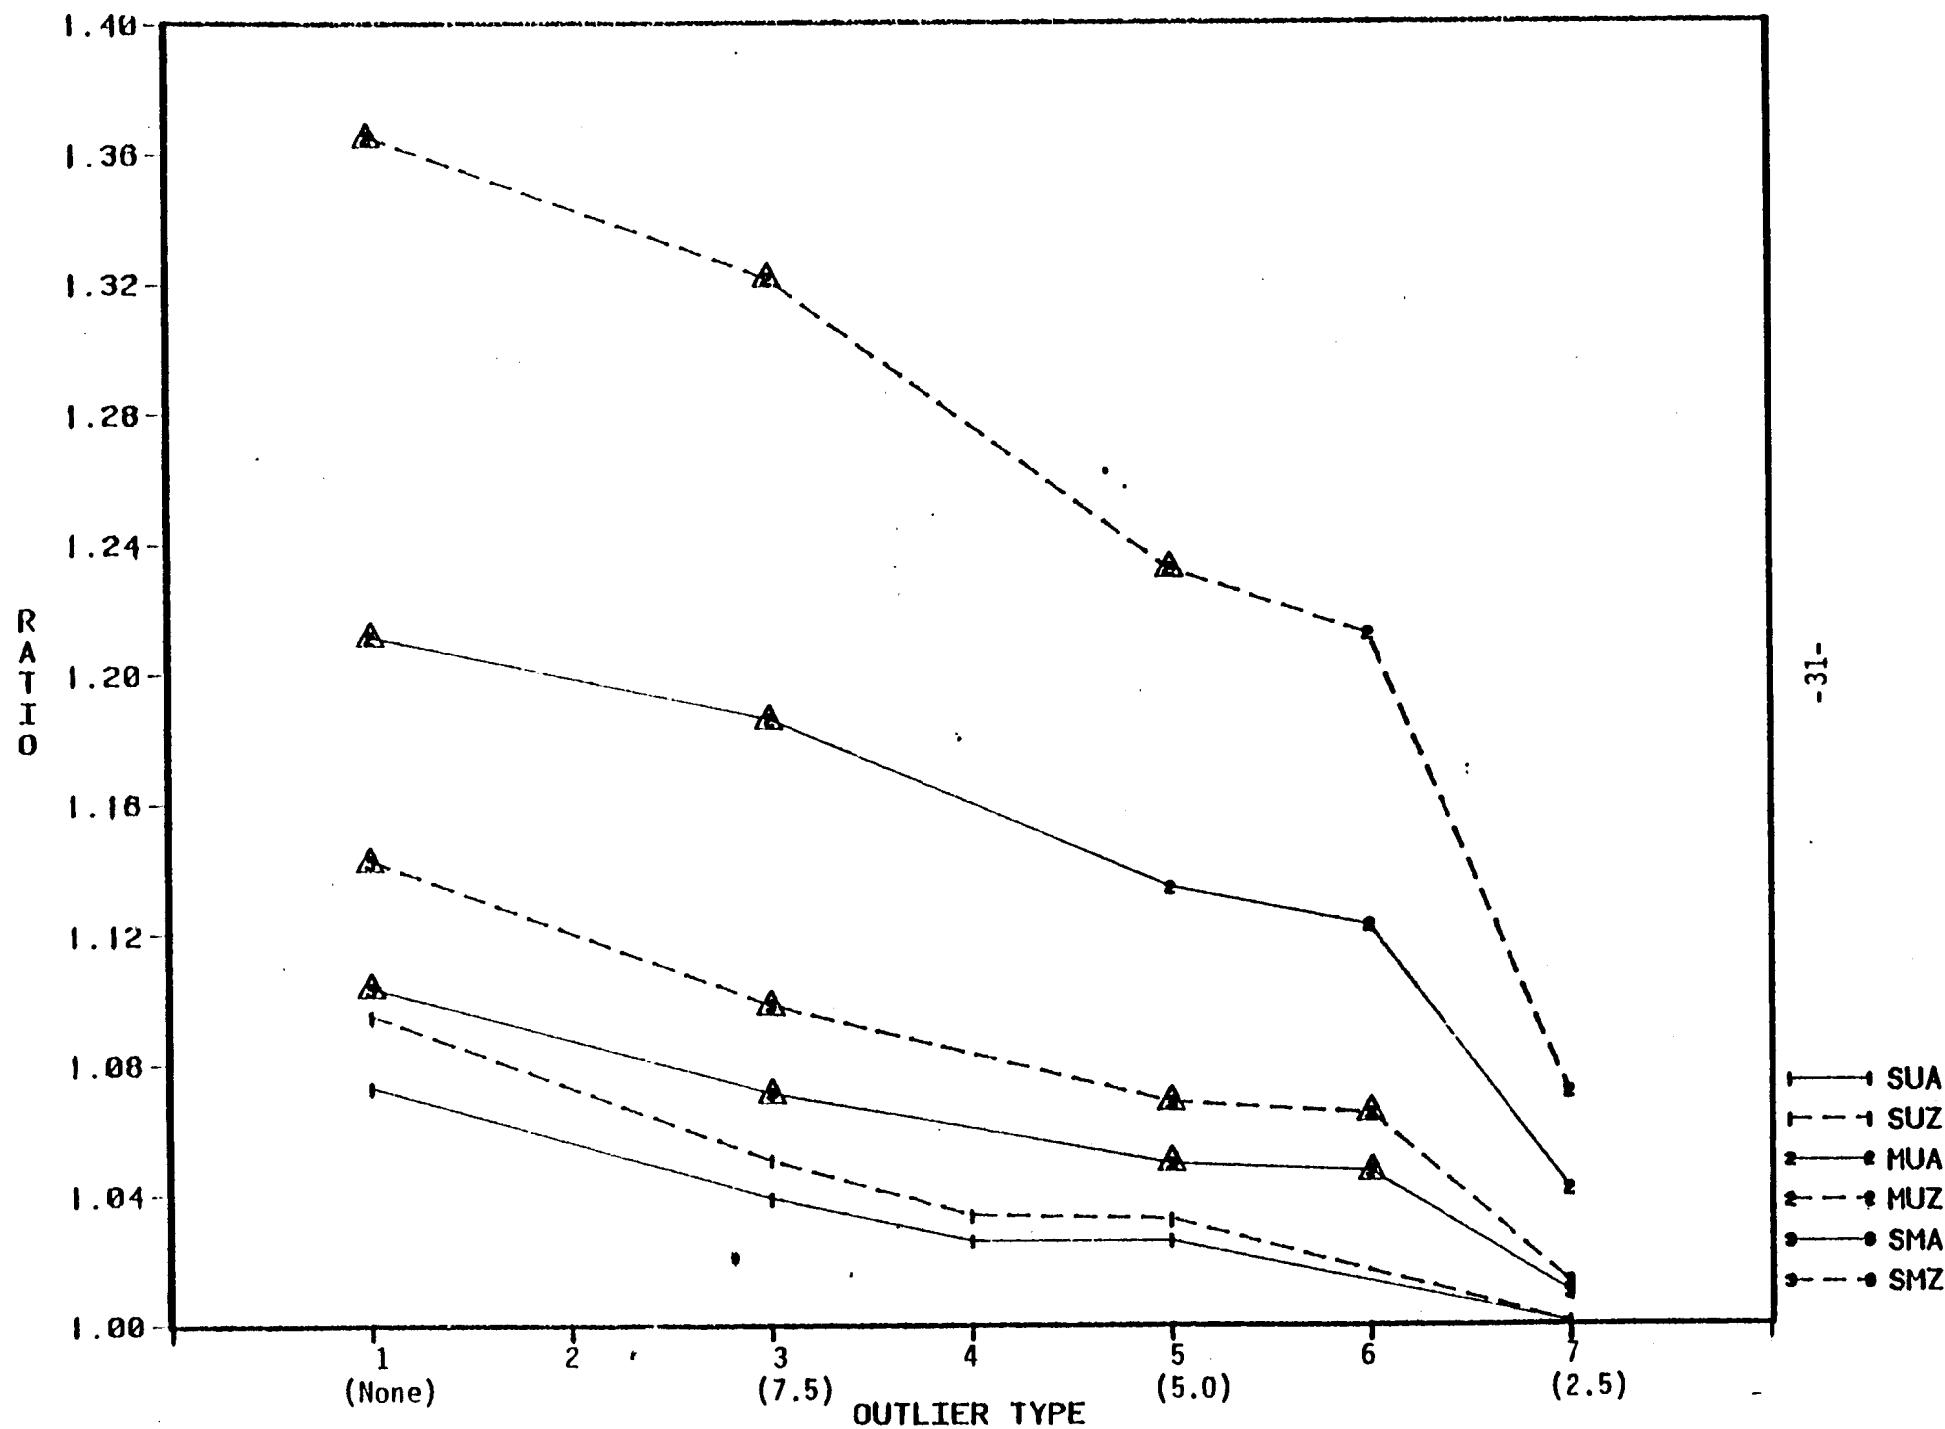

SERVICE INDUSTRIES - RECEIPTS

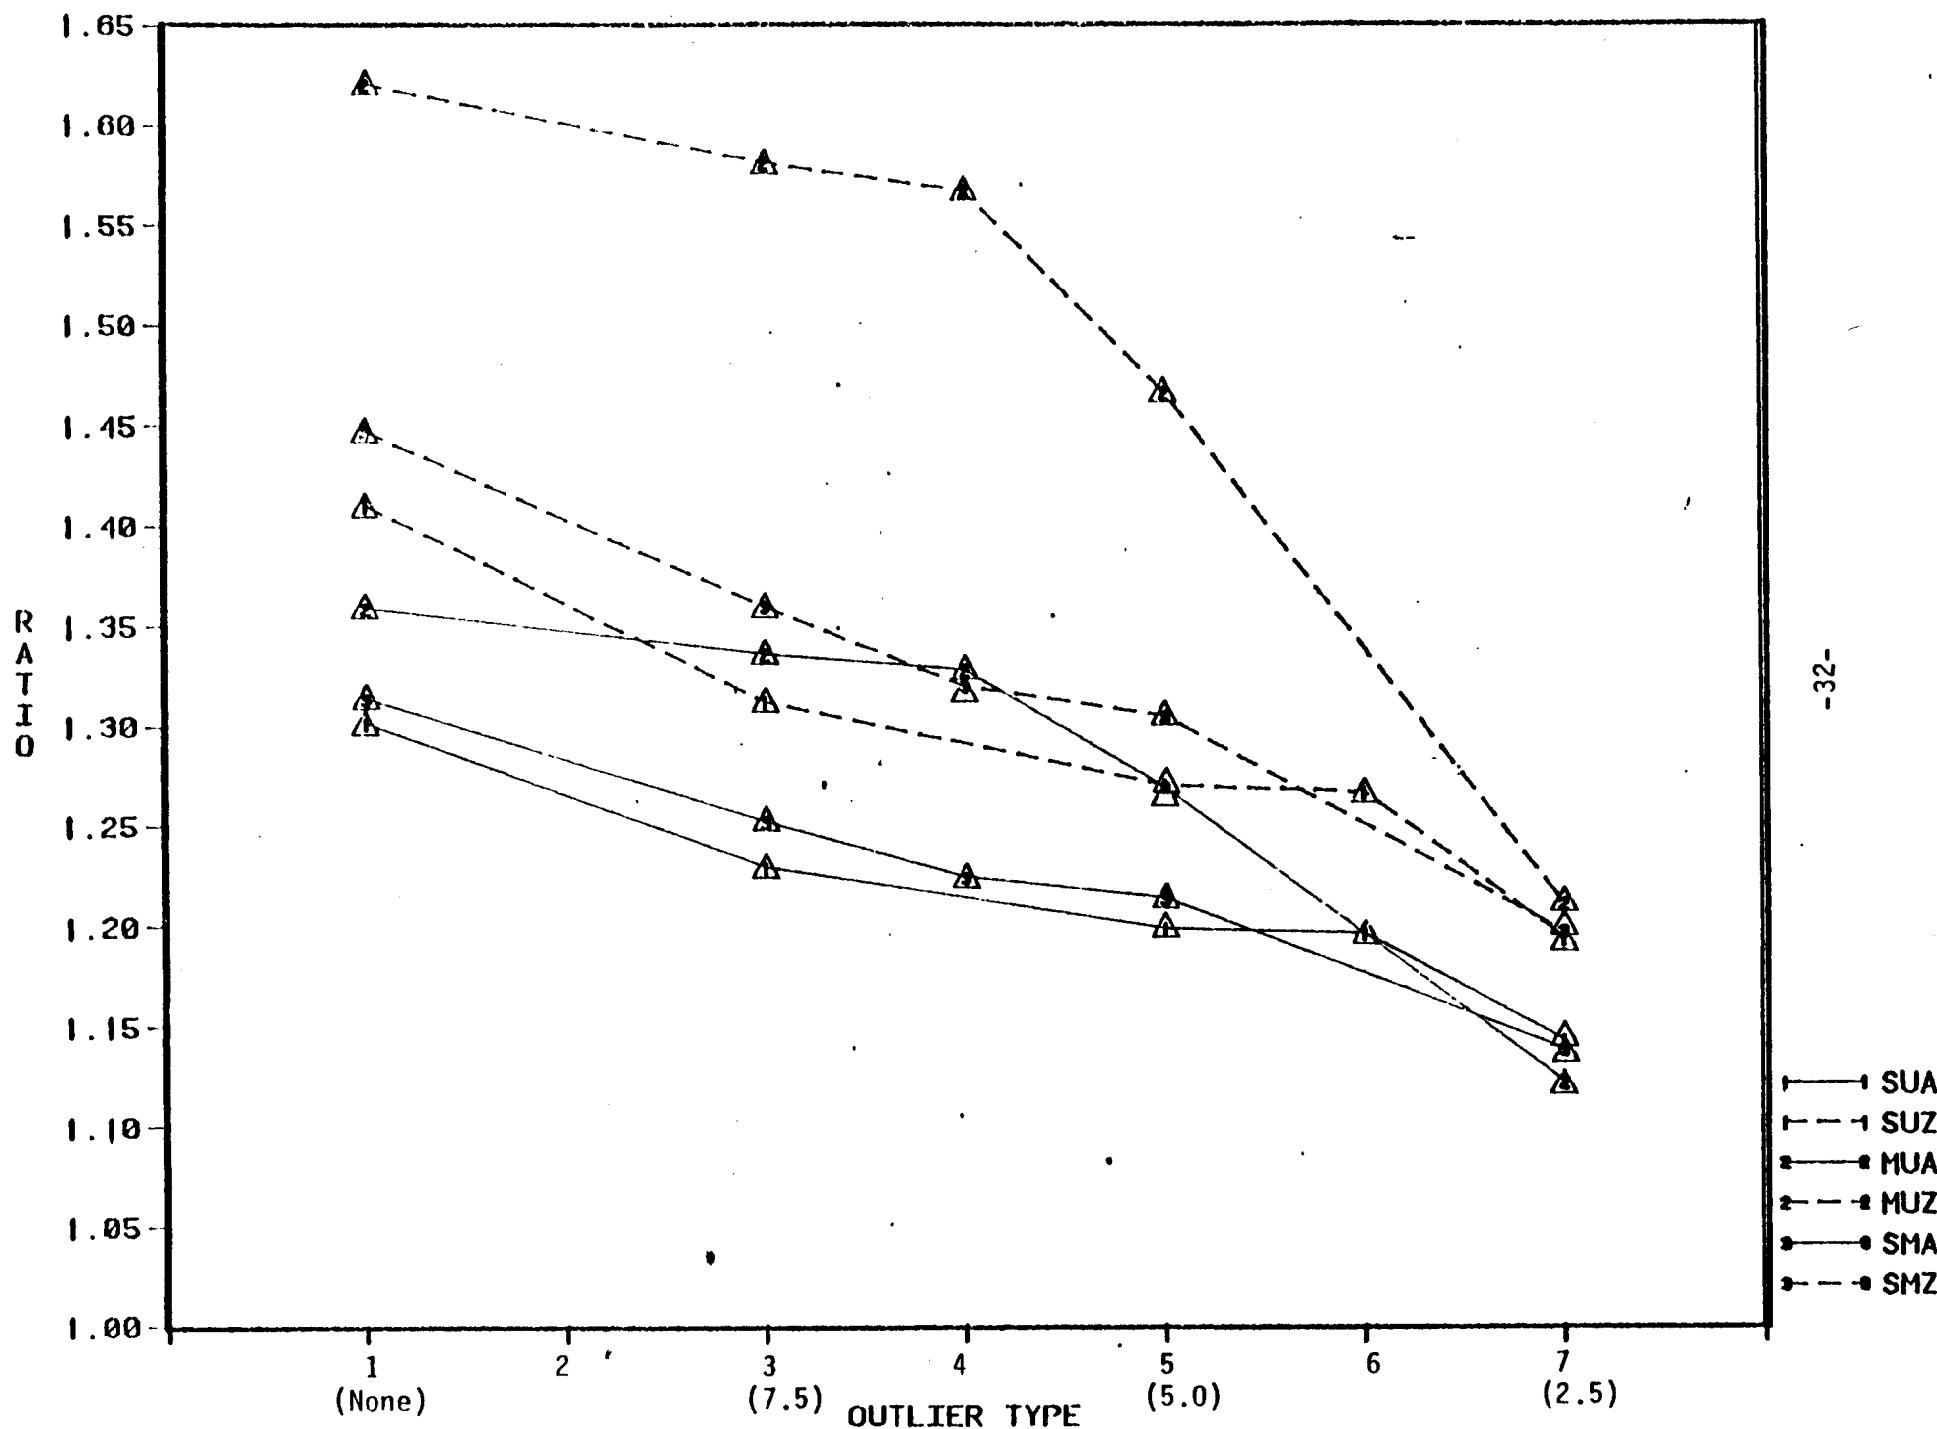

SERVICE INDUSTRIES - ANNUAL PAYROLL

SERVICE INDUSTRIES - IQ PAYROLL

SERVICE INDUSTRIES - IQ EMPLOYMENT

Appendix 1
Description of SIC Groupings

Wholesale Trade

- 50 - Durable goods
- 51 - Nondurable goods

The 1, 2, or 4 following the 2-digit SIC code is a type of operation code.

- 1 - Merchant wholesalers
- 2 - Manufacturers' sales branches and offices
- 4 - Agents, brokers, and commission merchants

Retail Trade

- 52 - Building Materials, Hardware, Garden Supply and Mobile Home Dealers
- 53 - General Merchandise Stores
- 554 - Gasoline Service Stations
- 55, 554 - Automotive Dealers (Group 55 except 554)
- 56 - Apparel and Accessory Stores
- 57 - Furniture Home Furnishings, and Equipment Stores
- 58 - Eating and Drinking Places
- 591 - Drug and Proprietary Stores
- 590 - Miscellaneous Retail - Durable goods including
 - 593 - Used Merchandise Stores
 - 594 - Sporting Goods, Bicycle, and Book, Jewelry, Hobby, Toys, Camera, Gift and Luggage Stores
- 59ND - Miscellaneous Retail - Nondurable goods including
 - 592 - Liquor stores
 - 5943 - Stationary stores
 - 596 - Nonstore Retailers (e.g. Mail order houses)
 - 598 - Fuel and Ice dealers
 - 599 - Florists, Cigar, and Newsstands

Service Industries

- 4722 - Arrangement of Passenger Transportation
- 70 - Hotels, Rooming Houses, Campass, Other Lodging
- 72 - Personal Services (Laundry, etc)
- 73 - Business Services
- 75 - Automotive Repair
- 76 - Miscellaneous Repair
- 78 - Motion Pictures
- 79 - Amusement and Recreative except Motion Pictures
- 80 - Health Services
- 81 - Legal Services
- 82 - Educational Services
- 83 - Social Services
- 86 - Membership Organizations
- 891, 892, 893, 899 - Engineering, Architectural, Surveying, Scientific Research, Accounting, Auditing and Bookkeeping Services.

Appendix 2

Tables of universe sizes, sampling weights, and sample sizes for Wholesale trade, Retail trade and Service Industries by type of unit, SIC code and stratification by sales/receipts.

Appendix 3
Graphical Representation of Outlier Adjustments

OUTLIER SCHEME

The data was processed five times

- 1 - No outlier adjustment
- 2 - Outlier factor = 7.5
- 3 - Outlier factor = 5.0
- 4 - Outlier factor = 2.5
- 5 - Outlier factor = 7.5 - "SPECIAL"
i.e. reported value set equal to administrative value.

Thus, depending on the process above
Point A would have 5 different values
Point B would have 3 different values
Point C would have 2 different values
Point D would never be altered.

The numbers near the point or arrow correspond to the particular process above.

Appendix 4

Tables of both types of ratio estimator, their standard errors, associated tests, and number of cases affected by outlier adjustment at each SIC level for single units, multiunits, and combined units. Tables are arranged by trade area, data items, and outlier adjustment procedure.
