

Evaluation of the 2005 Changes in the AHS Income Questionnaire

U.S. Department of Housing and Urban Development
Office of Policy Development and Research

Evaluation of the 2005 Changes in the AHS Income Questionnaire.

Scott Susin, HHES

September 18, 2007

Background

After redesigning the American Housing Survey (AHS) in 1997, the Census Bureau and the Department of Housing and Urban Development compared the income data collected in that survey with those found in the Current Population Survey (CPS).¹ That study found that the AHS reported fewer households with non-wage income than the CPS and that AHS respondents tended to report self-employment income as wages. In addition, AHS data users requested that disability-related income sources be reported separately from other sources, to make it easier to count the number of households with disabled persons.

The 2005 American Housing Survey addressed these findings and requests by adopting a series of income questions similar to the questions used in the American Community Survey (ACS).² Prior to 2005, respondents were asked the wages and salaries of each person in the family, and all other sources of income were collected as a single amount for the family as a whole. The 2005 questions collected an amount for each person in the family from nine different types of income (such as wages and salaries or social security). In addition, for each non-relative (a person not related to the householder), the 2005 questionnaire was changed to ask about wages, self-employment, and other income separately. Prior to 2005, non-relatives were asked only to report their total income. (See Table 1 for a comparison of the 2003 and 2005 AHS income questions.) The AHS chose to adopt the ACS questions because they had already been tested and to facilitate comparisons between the two surveys.

2003 AHS Compared to 2005 AHS

The approach for obtaining household and family income prior to the 2005 AHS resulted in reported income that was generally lower than in other surveys. In turn, Census Bureau surveys usually measure less aggregate income than is reported in the National Income and Product Accounts (NIPA).³ The new income questions were intended to more accurately collect income and were expected to increase the amount of income reported. Table 2 compares quantiles (percentiles) of household income in the 2005 AHS to the 2003 AHS.

¹ See Susin, Scott (2003) "Discrepancies Between Measured Income in the American Housing Survey (AHS) and the Current Population Survey (CPS): Final Report", March 27.
<http://www.census.gov/hhes/income/hudmemo8a.pdf>

² The AHS adopted the income categories used in the 2003 ACS with one change. Disability-related payments were accorded a separate item in the AHS, while the ACS included these types of payments with retirement and survivor pensions.

³ For a comparison of CPS and NIPA income, see Ruser, John, Adrienne Pilot, and Charles Nelson, (2004) "Alternative Measures of Household Income: BEA Personal Income, CPS Money Income, and Beyond," paper presented to the Federal Economic Statistics Advisory Committee (FESAC), December 14.
<http://www.bls.gov/bls/fesacp1061104.pdf>

Household income rose the most in the middle of the distribution while rising less, or even falling, in the tails of the distribution. Median household income rose by 9 percent from 2003 to 2005 in nominal terms (not adjusted for inflation). The 9 percent increase was 3 percentage points faster than inflation, suggesting that reported income increased in the middle of the distribution.

The 75th, 90th, and 95th percentiles rose at a slower rate than the median. The 75th percentile of household income increased by 4 percent, while the 90th percentile remained about the same (falling by 1 percent).⁴ The 95th percentile fell considerably and was 25 percent lower in 2005 than it had been in 2003. This probably indicates that fewer unrealistically large amounts are being reported due to the “range checks” implemented for the first time in 2005 that required respondents to confirm large income amounts.⁵ As we will see in Table 4, these upper (90th and 95th) percentiles had been higher than the ACS in 2003, but the two data sets became much closer after the AHS questionnaire revisions.

Table 2 also shows that the 10th percentile and 25th percentiles of household income rose at a slower rate than the 9 percent increase in the median or even the 6 percent inflation rate. Household income at both percentiles remained about the same. It is not surprising that the AHS finds the lower percentiles of household income rising more slowly than inflation because the same trend is present in the ACS, as shown in table 4 below. The AHS findings are also consistent with the increase in poverty rates shown in Table 5.

The 5th percentile of household income fell by 12 percent from 2003 to 2005, a drop too large to be consistent with the trends seen in other surveys. Hence, the amount of income reported at the very low end seems to have fallen, contrary to the increase expected due to the new questionnaire.

Family non-wage income rose sharply in all quantiles. In 2003 and earlier, non-wage income showed substantial underreporting compared to other surveys while reported wage and salary income was much closer to other surveys. Hence the increase in non-wage income was consistent with the improvements expected to be produced by the new questionnaire.

It is worth keeping in mind that much of the increase in non-wage income was probably due to a shift in the way that respondents reported self-employment income. A 2003 study (cited in footnote 1) comparing AHS and CPS income data found strong indications that substantial amounts of self-employment income were erroneously reported as wage and salary income. The new 2005 AHS questionnaire seems to have shifted some self-employment income to the correct line.

⁴ The 1 percent drop for the 90th percentile was not statistically significant.

⁵ For example, those who reported earning more than \$100,000 were asked to confirm the amount: “I have recorded that [Name] received \$[Amount Reported] in wages, salary, tips, bonuses, or commissions DURING THE PAST 12 MONTHS. Is this correct?”

Table 3 compares the rates at which different types of income were reported in the 2003 and 2005 AHS surveys. Between these years, 3.7 percentage points fewer families reported earnings, which was offset by an increase of 3.6 percentage points reporting self-employment income.⁶ As noted above, this probably indicates that households began reporting self-employment income in the correct category. The question referred to business income in 2003 but self-employment income in 2005, and it seems likely that many self-employed persons do not regard themselves as owning a business.

Table 3 also shows a large drop in reporting of interest income, dividend, and rental income, from 31.8 percent to 16.2 percent, probably due to a change in the questionnaire. In 2003, three separate questions were asked about these types of income, while in 2005, the questions were combined, and other types of income were added to the list as well, with the single question asking about interest, dividends, rental, estates, trusts, and royalties. Respondents might have incorrectly “keyed in” on the last few items in the list, and reported “no,” perhaps meaning “no royalties or trusts,” even when they had interest or dividend income.

In 2005, Social Security and pension income were split into two questions. From 2003 to 2005, the receipt rate for the combined income type rose from 26.9 to 28.9. Reporting of “other income” fell from 2003 to 2005, by 3.6 percentage points, possibly for similar reasons as for interest income, that is, because questions were combined. The list of “other” income types lengthened in 2005, to include alimony, which had previously been a separate question.

AHS Compared to Other Data Sets

Table 4 compares quantiles of household income in the AHS and the ACS.⁷ With the exception of the 5th percentile, the AHS percentiles were closer to the ACS in 2005 than they had been in 2003, or remained about the same.

The median and higher quantiles were similar in both the ACS and the AHS in 2005. In 2003, the AHS/ACS ratio was 0.93, indicating that the AHS median had been 7 percent below the ACS figure. In 2005 the AHS/ACS ratio had risen to 0.97, indicating that AHS median was only 3 percent below the ACS, suggesting that more income was reported in the middle of the AHS distribution.

The AHS 75th percentile was almost the same as the corresponding ACS figure in both 2003 and 2005 (AHS/ACS ratios of 1.00 and 0.99, respectively). The AHS 90th and 95th percentiles had been higher than the ACS in 2003. After the 2005 questionnaire revisions, both these percentiles fell relative to the ACS in 2005, becoming quite similar to the other survey. The fall in the 95th percentile was particularly dramatic. In 2003,

⁶ In this report, “earnings” refers to wage and salary income only and does not include self-employment income.

⁷ Both surveys ask about income in the prior 12 months, but the ACS operates year-round while most AHS interviewing occurs during a 3-month period. Table 4 presents ACS income reported during the months corresponding to the height of the AHS interviewing period (Jun – August, 2003 and May – July, 2005).

the AHS 95th percentile was 38 percent above the ACS, while in 2005 it was within 3 percent. As noted above, this suggests that the “range checks” have eliminated erroneous high values.

Household income at the 10th and 25th percentiles was smaller in the AHS than in the ACS. The ratios (88 and 92 percent in 2005) were about the same in both years. Hence the change in questionnaire made little difference in this range of incomes.

The 5th percentile fell by 10 percentage points, from a 0.72 ratio in 2003 to a 0.62 ratio in 2005. As noted above, this suggests an increase in unreported income (unreported to the AHS interviewer). This could indicate a modest increase in unreported income by extremely low income households. However, it might also indicate a large increase in unreported income by a few higher income households. For example, some households that subsist mainly on interest and dividend income may fail to report these sources of income, and end up with reported incomes far below their true incomes.

Table 5 compares poverty rates in the AHS, ACS, and CPS. The AHS and ACS data report poverty during the 12 months prior to Summer 2003 and 2005 (see footnote 4). The CPS data are for calendar years 2002 and 2004.

Household-level poverty in the AHS increased by 0.7 percentage points from 2003 to 2005. Family-level poverty increased by 0.4 percentage points.⁸ In both the CPS and ACS, family-level poverty rates increased by 0.6 percent.

Since the AHS poverty rate went up by about the same amount as the rate in the other two surveys, the AHS seems to be capturing about the same amount of income from poor households as in the past.

Note that there is no contradiction between the the possibility that the AHS is capturing about the same amount of income from poor households (as suggested by Table 5) and the 5th percentile figure falling relative to the ACS (as shown in Table 4). The poverty rate includes a much larger fraction of households (14 percent) than does the 5th percentile. The poverty rate findings are quite similar to the results for the 10th percentile. For low-income households, the revised income questionnaire has not had much effect on the amount of income reported.

New Income Imputation Scheme

The hot deck allocation (or imputation) method is widely used at the U.S. Census Bureau and other statistical agencies. In this method, the analyst specifies an allocation matrix based on characteristics thought to predict the variable being allocated. For example, in an allocation matrix predicting earnings, one cell might consist of white renters, aged 18-25, with a high school education. When earnings are not reported, they are imputed from the reported earnings of the last observation processed (typically geographically close) that falls in the same allocation cell.

⁸ The increase in AHS family poverty rates was not statistically significant.

The main drawback to hot deck imputation is that it considerably limits the number of variables that can be included as predictors. The size of the allocation matrix rapidly becomes very large as more predictors are added. Omitting *any* variable correlated with the imputed variable is undesirable, since this will bias the correlation between the omitted and imputed variable towards zero.⁹ In regressions of earnings on education, for example, the coefficient on education will be biased, presumably towards zero, if education is omitted from the allocation matrix.

Of particular importance here is that there is a strong relationship between the different types of income. For example, a worker earning a salary is unlikely to also receive retirement income (and vice versa). In other words, it is important to predict the receipt of each type of income based on whether the other types are received.

Due to these considerations, the 2005 AHS uses a “regression-based hot deck” to impute income. This method allows many more variables to be included as predictors, but retains the hot deck’s advantages of processing simplicity and ability to flexibly replicate the distribution of the data.

The method can be summarized as follows:

1. Estimate a regression predicting the variable to be imputed, using the sample of completely reported data (the donors).
2. Split the donor data into hot deck cells using the predicted values from the regression in (1). Choose cutpoints that put approximately 500 donor observations in each cell.
3. Apply the regression coefficients from (1) and the cutpoints in (2) to the cases with missing data, thus assigning each recipient case to a hot deck cell.
4. Impute the missing data by copying the value from the “last” donor case in the same hot deck cell as the recipient case. The data are sorted so that the last donor will typically be geographically close to the recipient.

In practice, the variables indicating receipt (yes/no) of each of the nine types of income are imputed first. Cases that answered one or more of the receipt questions, but not all of them, are imputed using a regression-based hot deck. Table 6 shows the regression variables, and Table 7 displays the particular variables in the regression equations for each of the nine receipt (yes/no) variables.

The income amount variables are imputed next. Because in many cases there is only one amount to be imputed, a separate set of regressions are used to create the hot deck for these cases. Table 8 displays the variables used in these regressions. Table 9 displays the variables in the regressions where there are two or more amounts to be imputed. Cases that declined to answer all the receipt questions have both receipts and amounts imputed using a traditional hot deck, as illustrated in table 10.

⁹ See, for example, Little, R. J. A. (1988), ‘Missing-data adjustments in large surveys’, *Journal of Business & Economic Statistics* 6, 287– 296.

Hot Deck Regressions

Tables 7-9 summarize a series of regressions with numerous explanatory variables and it may be instructive to go through a few columns. As an example, the first column of Table 9 describes the hot deck regressions for the amount of Social Security income. This regression was estimated in the sample of persons reporting all income information and is used to impute income to those reporting all the income information except for the Social Security amount. The “X” in the first row means that this regression includes an indicator for race. Table 6 shows that race includes 2 categories: white, non-Hispanic and minority. The next “X” in the Social Security column of Table 9 indicates that the regression includes a set of indicators for sex interacted with 5 Age categories. So there are 10 indicator variables, including one that is omitted from the regression. For instance, one of the indicators is for men aged 16-24. Skipping to the bottom panel, we see that there are few variables capturing other types of income. There is one indicator for the receipt of retirement income. The other income variables were excluded due to lack of statistical significance and the author’s judgment. The amount variables are shown after the comma. No amount variables are included because Social Security is the first income amount to be allocated and the other income amounts still include missing values.

Turning to the second, earnings, column of Table 9, we see that the earnings regression includes 4 age categories, rather than 5. For example, the 65-69 and 70+ categories used in the Social Security regressions are combined into a single 65+ category for the earnings regression (see Table 6). Another difference is that the earnings regression includes an indicator for whether the person worked in the previous week that was not included in the social security regression. The bottom panel shows that many receipt indicators were included in the earnings regression: Social Security, interest/dividends/rental income, SSI, welfare, self-employment, and other. Social Security amounts also enter into the regression. No other income amount variables are candidates for inclusion, since they have not been imputed yet.

Correlation Structure of Imputed Income

An evaluation of the imputation procedures is available separately.¹⁰ In brief, the new imputation procedure better captured the correlation structure of the data than the traditional hot deck. Specifically, the study compared the correlation among income types in the imputed data and the reported data in both the AHS and the ACS (which uses a traditional hot deck). In almost every instance, the AHS imputations better captured the correlation structure of the reported data, than did the ACS imputations.

¹⁰ Susin, Scott (2006). ”Imputation via Triangular Regression- Based Hot Deck,” 2006 Proceedings of the American Statistical Association, Section on Survey Research Methods [CD-ROM], Alexandria, VA: American Statistical Association.

In addition, the coefficients in a standard “wage regression” estimated with the imputed data showed substantially less bias in the 2005 AHS compared to either the 2003 AHS or the ACS. For example, the relationship between education and earnings in the 2005 AHS imputed data was very similar to the relationship in the reported data. By this measure, the ACS and older AHS imputations were less successful in reproducing the relationship between earnings and education found in the reported data.

Imputed Income Compared to Reported Income

The AHS asks about income in two steps, first asking a yes/no question about whether a particular type of income was received, and then asking for the amount. Table 11 compares the rates at which various types of income were received for reported and imputed data. The reported and imputed data are fairly similar. Because response rates for the yes/no receipt questions are high – 91 percent of families answer all receipt questions – these differences almost entirely disappear when comparing the reported data to the full sample data.

Table 12 presents quantiles of individual income amounts disaggregated into wage and non-wage income. Only those who received these types of income are included. Again, imputed and reported data are compared. Cases that are edited for consistency were tabulated separately, on the bottom panel.¹¹ They are excluded from the analysis here, because the editing often came after an imputation, and we are examining the imputation system here, not the combined imputation and editing systems.

Individual earnings tend to be lower in the imputed data than in the reported data, although the difference is slight in the higher percentiles. Individual non-wage earnings tend to be higher in the imputed data. Combining the two, total income is lower in the imputed data for the median and smaller quantiles, but reported and imputed income are quite similar at the 75th percentile and above. The distributions of the reported and imputed data will differ if the background characteristics of reporters and nonreporters differ. So it is not a surprise that income distributions differ somewhat between the reported and imputed data. Still, it is useful to know that the imputation procedures have only a modest effect on the income data.

When comparing the full sample to the reported data, the differences in the income amounts narrow, but not by as much as the receipt rates narrowed, since only 72 percent of families answered all the amount questions. There is little difference between the full sample and the reported data for the median and higher quantiles. For the 5th and 10th percentiles, full sample income is only 83% and 88% of reported income, respectively. However, the dollar amounts involved are small. For the 5th and 10th percentiles, full sample income is \$300 and \$600 lower than reported income, respectively.

¹¹ The consistency edits are most commonly invoked when a person reports a total income amount, but does not report complete information for all types of income. The edits allocate the total amount to the 9 categories of income.

Conclusion

For those with median or higher incomes, the revised AHS income questions resulted in data much closer to the ACS and other Census Bureau surveys, such as the CPS. There was little improvement, but also little deterioration, for most of those in the bottom half of the income distribution. For those with the lowest incomes (the bottom 5 percent) there was actually a fall in the amount of income reported. The 2007 AHS survey will address this issue by splitting the questions that combined multiple types of income and where reported rates of receipt declined sharply from previous years' surveys.¹²

The new imputation scheme appears to have better captured the relationship among income types, and between income and its predictors. This is welcome news, since many analyses are concerned with just such relationships. There should also be an improvement in the quality and accuracy of AHS cross-tabulations published by the Census Bureau.

¹² These two questions are those on "interest, dividends, net rental income, royalty income, or income from estates and trusts," and on "any other source such as Veteran's Administration (VA) payments, unemployment compensation, child support or alimony." These were split into "interest from savings, money market funds, IRA's, CDs, or other interest bearing accounts," "dividends from stocks," "rental income," "alimony or child support," and "unemployment compensation, any veteran's payments not already mentioned or any other income."

Table 1: Question Text for Income Items in the AHS National Survey

2003 (person level)	2005 (all items person-level)^a
In the past 12 months, how much did . . . earn in wages, salaries, tips, and commissions before deductions? (SAL)	During the past 12 months, did . . . receive any wages, salary, tips, bonuses or commissions? (QSAL) How much did...receive? (SALQ)
2003 (family level)	
In the past 12 months, did . . . have a business, farm or ranch? (QBUS)	Did . . . receive any self-employment income during the past 12 months? (QSELF) What was the amount? (SELFQ)
. . . receive Social Security/pensions? (QSS)	Did . . . receive any Social Security or Railroad Retirement benefits during the past 12 months? (QSS) What was the amount? (SSQ) Did . . . receive any retirement or survivor pensions during the past 12 months? (QRETIR) What was the amount? (RETIRQ)
. . . have interest from savings, money market funds, IRAs, CDs, other? (QINT) . . . have dividends from stocks? (QDIV) . . . receive rental income? (QRENT)	Did . . . receive any interest, dividends, net rental income, royalty income, or income from estates and trusts during the past 12 months? Report even small amounts credited to your account. (QIDRI) What was the amount received? (IDRIQ)
. . . receive SSI, public assistance or welfare payments such as [fill state program name]? (QWELF)	Did . . . receive any Supplemental Security Income (SSI) payments during the past 12 months? (QSSI) What was the amount? (SSIQ) Did . . . receive any public assistance or public welfare payments from the state or local welfare office during the past 12 months? (QWELF) What was the amount? (WELFQ)
. . . receive workers' compensation or other disability payment? (QWKCMP)	Did . . . receive any disability payments such as SSDI, workers' compensation, veterans' disability or other disability payments during the past 12 months? (QWKCMP) What was the amount? (WKCMPO)
. . . receive alimony/child support? (QALIM) . . . receive unemployment compensation, veterans's payments not already mentioned or any other income? (QOTHER)	Did . . . receive income on a REGULAR basis from any other source such as Veterans' Administration (VA) payments, unemployment compensation, child support or alimony during the past 12 months? (QOTALM) What was the amount from all sources? (OTALMO)
In the past 12 months, what was the total income from: [source 1, source2, etc.] ?	

^a 2005 Questions are not presented in the same order as on the questionnaire.

Table 2: Quantiles of Income: 2003 vs. 2005 AHS

Ratio: Full Sample 2005/2003

	N	5th	10th	25th	Median	75th	90th	95th

Family Non-Wage Income	27,086	50	226	2,500	9,900	22,332	49,000	74,000

Full Sample: 2005 AHS

	N	5th	10th	25th	Median	75th	90th	95th
Household Income	43,360	4,200	9,468	21,156	43,850	77,000	119,000	154,000
Family Income	42,592	6,000	9,900	20,700	42,000	75,000	116,000	151,500
Family Earnings	32,050	5,000	11,000	24,000	45,000	75,000	115,000	149,500
Family Non-Wage Income	23,585	315	1,000	5,100	13,000	29,000	55,000	80,000

NOTE: Sample excludes zero amounts.

Table 3: Family Income Receipt Rates, by Income Types. 2003 vs. 2005 AHS.

	Proportion			Note on change from 2003 to 2005.
	AHS 2005	AHS 2003	Difference	
Social Security and Pensions	0.289	0.269	0.020	SS and pensions were combined in 2003, split into 2 questions in 2005.
Wages and Salaries	0.747	0.785	-0.037	
Social Security	0.256			
Interest, Dividends, Rental Income	0.162	0.318	-0.156	These were 3 questions in 2003, combined into one in 2005.
Supplemental Security Income	0.038			
Welfare	0.022	0.047		Welfare and SSI were combined in 2003, split into 2 questions in 2005
Workers' Compensation	0.049	0.030	0.019	
Self-Employment	0.131	0.095	0.036	In 2003, question referred to business income. In 2005, it refers to self-employment.
Other Income	0.068	0.103	-0.036	Other income and alimony were 2 questions in 2003, combined into one in 2005.
Sample Size	43,360	48,197		

NOTE: Data is weighted. Receipt of income by family members only, excluding nonrelatives of the householder.

Table 4: Quantiles of Household Income. ACS vs. AHS, 2003 to 2005.

	N	Mean	Std. Dev.	5th	10th	25th	Median	75th	90th	95th
Ratio of 2005 AHS/ACS		0.97	1.18	0.62	0.88	0.92	0.97	0.99	0.99	0.97
Ratio of 2003 AHS/ACS		1.08	2.24	0.72	0.89	0.94	0.93	1.00	1.06	1.38
2005 AHS	43,360	59,477	85,541	4,200	9,468	21,156	43,850	77,000	119,000	154,000
2005 ACS ^a	461,220	61,170	72,620	6,768	10,768	23,000	45,000	78,000	120,100	159,490
2003 AHS	48,197	62,263	142,146	4,800	9,477	20,760	40,124	74,000	120,000	205,000
2003 ACS ^b	139,376	57,493	63,479	6,648	10,611	22,105	43,155	74,000	113,158	148,097

NOTES: a. 2005 ACS interviews during the main AHS interviewing period (May, June, and July).
b. 2003 ACS interviews during the main AHS interviewing period (June, July, and August).

Table 5: Poverty Rates Across Surveys

	Households (1000s)		Percent in Poverty		
	2003	2005	2003	2005	Difference
AHS Households	105,874	108,901	13.2	13.9	0.7
Family Households					
AHS ^a	71,639	73,409	10.9	11.3	0.4
CPS ^b	75,616	77,019	9.6	10.2	0.6
ACS ^c	73,530	75,606	9.8	10.4	0.6

NOTE: AHS, CPS, and ACS poverty estimates are not exactly comparable. The table reports poverty in family households for all three surveys, but the AHS poverty measure is household income as a percent of poverty level for the household members, while the other two surveys use family income as a percent of poverty level for the family members.

- a. Income for the 12 months prior to the interview period (Summer 2003 and 2005).
- b. Income for calendar years 2002 and 2004.
- c. Income for the 12 months prior to the interviewing period. Data include only interviews during the main AHS interviewing period (June, July, and August in 2003; May, June, and July in 2005).

Table 6: Income Predictor Variables and Values Used for 2005 AHS Regression-Based Hot Deck

Income Predictor Variable	Possible Values
Worked	Yes/No
Sex	Male/Female
Race	White, Non-Hispanic/Minority
Age4	16-18/19-24/25-64/65+
Age5	16-24/25-61/62-64/65-69/70+
Tenure	Own/Rent
Housing Cost	lowest quartile/2nd quartile/3rd quartile/highest quartile
Relationship to Householder	Head/Spouse/Child/Parent/Sibling or Other
Family Type	Single Mother/Married/Other
Kids	0/1/2/3+
Education	< High School/High School/Some College/College or more
Married	Married/Divorced/Widowed/Never/Missing
Citizen	Yes/No
9 Income Receipt Indicators	Yes/No
9 Income Amounts	Logarithm of positive amounts, otherwise zero

Table 8: Variables in Amount Regressions for Those With Only 1 Amount to be Allocated

Table 10: Allocation Matrix for Family Non-reporters: Cell Sample Sizes for Complete Reporters

	Head/Spouse						Other Family Member					
	Age < 25		Age 25-64		Age > 64		Age < 25		Age 25-64		Age > 64	
	Male	Female	Male	Female	Male	Female	Male	Female	Male	Female	Male	Female
Worked, Lowest Productivity Quintile	351	657	159	1,545					234	275		
Worked, 2nd Productivity Quintile	277		1,388	4,499	303	318					combined with Head/Spouse	
Worked, 3rd Productivity Quintile			2,861	3,747			1,516	1,351	637	336		
Worked, 4th Productivity Quintile	140	180	4,276	2,558	316	138						
Worked, Highest Productivity Quintile			6,102	696								
No Work, Lowest Productivity Quintile				2,014	150	1,976						
No Work, 2nd Productivity Quintile			668	2,897	685	1,640						
No Work, 3rd Productivity Quintile	180	546	810	1,817			2,423	2,331	677	732	146	397
No Work, 4th Productivity Quintile			788	1,104	2,171	791						
No Work, Highest Productivity Quintile			780	230								

Note: The rows indicate whether a person worked last week and their quintile of predicted wages. Productivity Quintiles are based on predicted earnings from a regression of the logarithm of annual earnings on Sex*Race, a quartic in age, Tenure*Housing Cost, Relationship to Householder*Family Type, Relationship to Householder*Kids, and Sex*Education.

Table 11: Proportion of Individuals Receiving Income Types, by Imputation Status. 2005 AHS

	Full Sample	Responded	Imputed	Difference	Response Rate
Social Security and Retirement	0.181	0.181	0.179	-0.002	0.95
Wages and Salaries	0.621	0.622	0.593	-0.029	0.96
Social Security	0.084	0.084	0.090	0.006	0.95
Interest, Dividends, Rental Income	0.101	0.101	0.100	-0.001	0.93
Supplemental Security Income	0.022	0.022	0.023	0.001	0.95
Welfare	0.012	0.012	0.010	-0.002	0.95
Workers' Compensation	0.028	0.027	0.028	0.001	0.95
Self-Employment	0.079	0.081	0.056	-0.025	0.95
Other Income	0.038	0.039	0.026	-0.012	0.95

Notes: Data are weighted. Sample Size is 80,615 individuals 16 years or more years of age. Nonrelatives are excluded.

Table 12: Quantiles of Individual Income for Persons with Non-Zero Amounts, by Edit/Imputation Status. 2005 AHS

Ratio: Imputed/Responded								
	N	5th	10th	25th	Median	75th	90th	95th
Earnings		0.75	0.72	0.80	0.90	0.96	0.96	0.98
