ABSTRACT

Survey of Income and Program Participation
(SIPP) Wave 8 Rectangular Core and Topical Module
Microdata File [machine-readable data file] /
conducted by the U.S. Bureau of the Census.
- Washington: The Bureau [producer and distributor],
1988.

Type of File:

Microdata; unit of observation is an individual.

Universe Description:

The universe is the resident population of the United States, but excluding persons living in institutions and military barracks.

Subject-Matter Description:

The file contains basic demographic and social characteristics data for each member of the household. These include age, sex, race (White; Black; American Indian, Eskimo, and Aleut; Asian or Pacific Islander; and Other), ethnic origin (23 categories including 7 Spanish origin categories), marital status, household relationship, education, and veteran status.

Limited data are provided on housing unit characteristics such as units in structure, tenure, access, and complete kitchen facilities.

Core questions, which are repeated at each interview, cover labor force activity, types and amounts of income, and participation in various cash and noncash benefit programs for each month of the four-month reference period. Data for employed persons include number of hours and weeks worked, earnings, and weeks without a job. Nonworkers are classified as unemployed or not in the labor force. In addition to income data associated with labor force activity, data include nearly 50 other types of income. Core data also cover post secondary school attendance, public or subsidized rental housing, low-income energy assistance, and school breakfast and lunch participation.

Persons interviewed in Wave 8 were asked the core questions as well as questions on support for nonhousehold members, work-related expenses, marital history, migration history, fertility history, and household relationships. Support for nonhousehold members includes data for children and adults not in the household. Weekly and annual work-related expenses are documented. Widowhood, divorce, separation, and marriage dates are part of the marital history. Birth expectations as well as dates of birth for all the householder's children, in the household or elsewhere, are recorded in the fertility history. Migration history contains birth history of the householder's parents, number of times moved, and moving expenses. Household relationships lists the exact relationships among persons living in the household.

The sample consists of 4 rotation groups, each interviewed in a different month from September to December 1985. For each group the reference period for reporting labor force activity and income is the four calendar months preceding the interview month.

SIPP is a longitudinal survey where each sampled household and each descendent household is reinterviewed at 4-month intervals for 9 interviews or "waves." This file contains the results of the eighth interview. Unique codes are included on each record to allow linking together the same persons with the preceding and subsequent waves.

Geographic Coverage:

United States. Codes are included for 38 individual States, although the sample was not designed to produce State estimates. Areas in the SIPP sample in six other States are identified in two groups for confidentiality reasons. Some cases are coded to other States not originally sampled, reflecting persons in the original sample who moved. The file identifies a subsample of metropolitan residents, along with codes for selected metropolitan statistical areas (MSA's) and consolidated metropolitan statistical areas (CMSA's).

Technical Description:

File Structure: Rectangular. Each logical record for a sampled person includes information on the household and family of which the person was a part during each month of the reference period, as well as characteristics of the person and each source of income received during the period.

File Size: 32,334 logical records; 6,224 character logical record length.

File Sort Sequence

of Sample Units: Rotation group (i.e., month of interview) by FIPS State of sampling unit within rotation group by sampling unit identification number within State by entry address ID and person number within sampling unit.

FILE INFORMATION

Geographic Coverage

State codes are shown except for six States which are identified in two groups. A subsample of metropolitan residents is identified along with codes for selected metropolitan statistical areas (MSA's) and consolidated metropolitan statistical areas (CMSA's). The sample was not designed to produce State or MSA/CMSA level estimates. State codes are primarily useful in relating a respondent's reciprocity of benefits to thresholds which may vary from State to State. MSA/CMSA codes may be used in relating respondent characteristics with contextual variables.

Identification Number System

The SIPP identification scheme is designed to uniquely identify individuals in each wave, provide a means of linking the same individuals over time, and group individuals into households and families over time.

The various components of the identification scheme are listed below:

- Sample Unit Identification Number
- Address ID
- Entry Address ID
- Person Number

The sample unit identification number was created by scrambling together the PSU, segment, and serial numbers used for Census Bureau administrative purposes. This identifier is constructed the same way on each wave regardless of moves, to enable matching from wave to wave.

The two-digit address ID code identifies each household associated with the same sample unit identification number. The first digit of the address ID code indicates the wave in which that address was first assigned for interview. The second digit sequentially numbers multiple households that have the same serial number. The address ID code is 11 for all sample addresses that are the same as in Wave 1. As SIPP sample persons move to new addresses, new address ID codes are assigned. Any new address to which sample unit members moved during Wave 4 is numbered in the 40's.

The person ID is a five-digit number consisting of the two-digit entry address ID and a three-digit person number. Person numbers 101, 102, etc., are assigned in Wave 1; 201, 202, etc., are assigned to persons added to the roster in Wave 2, and so forth. This five-digit number is not changed or updated, regardless of moves.

The sampling unit serial number and address ID code uniquely identifies each household in any given wave. The sampling unit serial number can link all households in subsequent waves back to the original Wave 1 household.

Topcoding of Income Variables

To protect against the possibility that a user might recognize the identity of a SIPP respondent with very high income, income from every source is "topcoded" so that no individual income amounts above \$100,000 are revealed. While the data dictionary indicates a topcode of \$33,332 for monthly income, this topcode will rarely be used. In most cases the monthly income is shown as an individual dollar amount of \$8,333, with \$8,333 actually representing "\$8,333 or more." (The \$100,000 annual income topcode is \$8,333 multiplied by 12 months). Individual monthly amounts above \$8,333 may occasionally be shown if the respondent's income varied considerably from month to month, as long as the average does not exceed \$8,333. For example, if a

respondents' income from a single job were concentrated in only one of the four reference months, a figure as high as \$33,332 could be shown. (Income from interest or property have lower topcodes).

Summary income figures on the person, family, and household records are simple sums of the components shown on the file after topcoding, and are not independently topcoded. Thus, a person with high income from several sources (jobs, businesses, property) could have aggregate monthly income well over the topcode for each source. Families and households with a number of high income members could theoretically have aggregate income shown well over \$100,000, through well below the \$1.5 million shown as the highest allowable value in the data dictionary.

The user is cautioned against trying to make much use of the occasional monthly figures above \$8,333, except in calculating aggregates or observing patterns across the 4-month period for a single individual, family, or household. Those units with higher monthly amounts shown are a biased sample of high income units, more likely to include units with income from multiple sources than other units with equally high aggregate income which comes from a single source.

HOW TO USE THE DATA DICTIONARY

The Data Dictionary describes the contents and record layout of the public-use computer tape file. The first line of each data item description gives the data name, size of the data field, and the begin position of the field.

The next few lines contain descriptive text and any applicable notes. Categorical value codes and labels are given where needed. Comment notes marked by an (*) are provided throughout. Comments should be removed from the machine-readable version of the data dictionary before using it to help access the data file.

DATA. 8 characters—alphabetic, numeric, and the special character (-). No other special characters are used. It may be a mnemonic such as "HI-STATE" or "SE-OCC", or a sequential identifier such as "SC3138" or "WS-IMPO1." Data item names are unique throughout the entire file.

SIZE. 9 characters—numeric. The size of a data item is given in characters. Indication of implied decimal places is provided in notes.

BEGIN. 9 characters—numeric. Contains the location in the data record of the first character position of the data item field.

The first line of the data item description begins with the character "D" (left-justified, two characters). The "D" flag indicates lines in the data dictionary containing the name and location (size and begin) position of each data item. This information (in machine-readable form) can be used to help access the data file. The line beginning with the character "U" describes the universe for that item. Lines containing categorical value codes and labels follow the universe description and begin with the character "V". The special character (.) denotes the start of the value labels. Two examples of data item descriptions follow:

```
D WS1-2030      1      3297
    During the 4-month period how often
    was...paid on the job?
U Persons 15 years old and older
V 0 .Not in universe
  1 .Once a week
  2 .Once each 2 weeks
  3 .Once a month
  4 .Twice a month
  5 .Some other way

D WEEKSLK      18      2525
    Was this person looking for work
    or on layoff during this week of the
    reference period. There are 18 answer
    fields, one for each week of the
    reference period.
U Persons 15 years old or older
V 0 .Not applicable
  1 .Yes
  2 .No

SOURCE AND RELIABILITY STATEMENT FOR THE SURVEY OF INCOME AND PROGRAM PARTICIPATION (SIPP) WAVE 8 1984 PUBLIC USE FILE

Source of Data

The data were collected in the eighth interview wave of the 1984 panel of the Survey of Income and Program Participation (SIPP). The SIPP universe is the noninstitutionalized resident population living in the United States. This population includes persons living in group quarters, such as dormitories, rooming houses, and religious group dwellings. Crew members of merchant vessels, Armed Forces personnel living in military barracks, and institutionalized persons, such as correctional facility inmates and nursing home residents, were not eligible to be in the survey. Similarly, United States citizens residing abroad were not eligible to be in the survey. Foreign visitors who work or attend school in this country and their families were eligible; all others were not eligible to be in the survey. With the exceptions noted above, persons who were at least 15 years of age at the time of the interview were eligible to be in the survey.

The 1984 panel SIPP sample is located in 174 areas comprising 450 counties (including one partial county) and independent cities. Within these areas, clusters of 2 to 4 living quarters (LQs) were systematically selected from lists of addresses prepared for the 1970 decennial census to form the bulk of the sample. To account for LQs built within each of the sample areas after the 1970 census, a sample was drawn of permits issued for construction of residential LQs through March 1983. In jurisdictions that do not issue building permits, small land areas were sampled and the LQs within were listed by field personnel and then subsampled. In addition, sample LQs were selected from supplemental frames that included mobile home parks and new construction for which permits were issued prior to January 1, 1970, but for which construction was not completed until after April 1, 1970.

Approximately 26,000 living quarters were originally designated for the sample. For Wave 1, interviews were obtained from the occupants of about 19,900 of the 26,000 designated living quarters. Most of the remaining 6,100 living quarters were found to be vacant, demolished, converted to nonresidential use, or otherwise ineligible for the survey. However, approximately 1,000 of the 6,100 living quarters were not interviewed because the occupants refused to be interviewed, could not be found at home, were temporarily absent, or were otherwise unavailable. Thus, occupants of about 95 percent of all eligible living quarters participated in Wave 1 of the survey.

For the subsequent waves, only original sample persons (those interviewed in the first wave) and persons living with them were eligible to be interviewed. With certain restrictions, original sample persons were to be followed if they moved to a new address. All noninterviewed households from Wave 1 were automatically designated as noninterviews for all subsequent waves. When original sample persons moved without leaving a forwarding address or moved to extremely remote parts of the country, additional noninterviews resulted.

Sample households within a given panel are divided into four subsamples of nearly equal size. These subsamples are called rotation groups, denoted R (R = 1, 2, 3, or 4), and one rotation group is interviewed each month. Each household in the sample was scheduled to be interviewed at 4-month intervals over a period of 2 1/2 years beginning in October 1983. The reference period for the questions is the 4-month period preceding the interview. In general, one cycle of four interviews covering the entire sample, using the same questionnaire, is called a wave. However, Wave 8 contains only interviews for rotation groups 1, 2, and 4.

The Wave 8 public use file includes core data and supplemental (topical module) data. Core questions are repeated at each interview over the life of the panel. Topical modules include questions which are not asked every month. The Wave 8 topical module covers (1) Marital History, (2) Migration History, (3) Fertility History, (4) Household Relationships, and (5) Support for Non-household Members/Work-Related Expenses.

Table 1 indicates the reference months and interview month for the collection of data from each of the three rotation groups in Wave 8. For example, rotation group 2 was interviewed in March 1986 and data for the reference months November 1985 through February 1986 were collected.

The estimation procedure used to derive SIPP person weights involves several stages of weight adjustments. These include determining the base weight, adjusting for movers and noninterviews, adjusting to account for the SIPP sample areas not having the same population distribution as the strata from which they were selected and adjusting persons' weights to bring sample estimates into agreement with independent population estimates.

Each person received a base weight equal to the inverse of his/her probability of selection. The SIPP base weight *W* indicates that each SIPP sample person represents approximately *W* persons in the SIPP universe. Due to funding difficulties, a sample cut of 17.8 percent was implemented in March 1985. Each rotation group was reduced by about 850 interviewed housing units. Both self-representing (SR) PSUs and nonself-representing (NSR) PSUs were subject to the cut. In some instances, the base weight was adjusted to reflect subsampling done in the field. For each subsequent interview, each person received a base weight that accounted for following movers.

A noninterview adjustment factor was applied to the weight of each interviewed person to account for persons in occupied living quarters who were eligible for the sample but were not interviewed. (Individual nonresponse within partially interviewed households was treated with imputation. No special adjustment was made for noninterviews in group quarters.)

A first stage ratio estimate factor was applied to each interviewed person's weight to account for the SIPP NSR sample areas not having the same population distribution as the strata from which they were selected. In particular, the first stage ratio estimate factors ensure proportional representation by race and by metropolitan and nonmetropolitan residence defined as of June 1981.

An additional stage of adjustment to persons' weights was performed to bring the sample estimates into agreement with independent monthly estimates of the civilian (and some military) noninstitutional population of the United States by age, race, and sex. These independent estimates were based on statistics from the 1980 Decennial Census of Population; statistics on births, deaths, immigration, and emigration; and statistics on the strength of the Armed Forces. Weights were further adjusted so that sample estimates would agree with special Current Population Survey (CPS) estimates of the prevalence of different types of householders (married, single with relatives or single without relatives by sex and race) and different relationships to householders (spouse or other). Also, husbands and wives were assigned equal weights. As a result of these adjustments, the following types of consistency are attained by race and sex on a monthly basis:

1. The sum of weights of civilian (and some military) noninstitutionalized persons agrees with independent estimates by age groups.
2. The sum of weights of civilian (and some military) noninstitutionalized persons is within a close tolerance of special CPS estimates by householder type and relationship to householder. (The special CPS estimates are similar but not identical to the monthly CPS estimates.)

3. Husbands and wives living together have equal weights. Thus, if a characteristic is necessarily shared by a husband and wife (such as size of family), then the sample estimate of the number of husbands with the characteristic will agree with the corresponding estimate for wives.

Use of Weights. Each household and each person within each household on the Wave 8 tape has five weights. Four of these weights are reference month specific and therefore can be used only to form reference month estimates. To form an estimate for a particular month, use the reference month weight for the month, summing over all persons or households with the characteristic of interest whose reference period includes that month. Multiply the sum by a factor to account for the number of rotations contributing data for the month. This factor equals four divided by the number of rotations contributing data for the month. For example, November and December data are only available from rotations 1, 2, and 4 (see Table 1), so a factor of $4/3$ must be applied. October and January data are available from two rotations, so a factor of $4/2 = 2$ must be applied. Reference month estimates can be averaged to form estimates of monthly averages over some period of time. For example, using the proper weights, one can estimate the monthly average number of households in a specified income range over October and November 1985.

The remaining weight is interview month specific. This weight can be used to form estimates that specifically refer to the interview month (e.g., total persons currently looking for work), as well as estimates referring to the time period including the interview month and all previous months (e.g., total persons who have ever served in the military). There is no weight for characteristics that involve a person's or household's status over two or more months (e.g., number of households with a 50 percent increase in income between October and November 1985).

When estimates for all months are constructed from Wave 8 data, factors greater than 1 must be applied. However, when the Wave 8 core data are used in conjunction with the Wave 7 and Wave 9 core data, data from all four rotations will be available for August through March, and the factors will equal 1 for those months.

To estimate monthly averages of a given measure (e.g., total, mean) over a number of consecutive months, sum the monthly estimates and divide by the number of months.

Producing Estimates for Census Regions. The total estimate for a region is the sum of the state estimates in that region. However, one of the groups of states formed for confidentiality reasons crosses regional boundaries. This group consists of South Dakota (Midwest Region), Idaho (West Region), New Mexico (West Region), and Wyoming (West Region). To compute the total estimate for the Midwest Region, a factor of 0.203 should be applied to the above group's total estimate and added to the sum of the other state estimates in the Midwest Region. For the West Region, a factor of 0.797 should be applied to the above group's total estimate and added to the sum of the other states in the West Region.

Estimates from this sample for individual states are subject to very high variance and are not recommended. The state codes on the file are primarily of use for linking respondent characteristics with appropriate contextual variables (e.g., state-specific welfare criteria) and for tabulating data by user-defined groupings of states.

Producing Estimates for the Metropolitan Population. For 15 states in the SIPP sample, metropolitan or nonmetropolitan residence is identified (Variable H*-METRO, characters 94, 382, 670, and 958). In 21 additional states, where the nonmetropolitan population in the sample was small enough to present a disclosure risk, a fraction of the metropolitan sample was recoded so as to be indistinguishable from nonmetropolitan cases (H*-METRO=2). In these states, therefore, the cases coded as metropolitan (H*-METRO=1) represent only a subsample of that population.

In producing state estimates for a metropolitan characteristic, multiply the individual, family, or household weights by the metropolitan inflation factor for that state presented in Table 4. (This inflation factor compensates for the subsampling of the metropolitan population and is 1.0 for the states with complete identification of the metropolitan population.)

The same procedure applies when creating estimates for particular identified MSA's or CMSA's—apply the factor appropriate to the state. For multi-state MSA's, use the factor appropriate to each state part. For example, to tabulate data for the Washington, DC-MD-VA MSA, apply the Virginia factor of 1.0778 to weights for residents of the Virginia part of the MSA; Maryland and Washington, DC residents require no modification to the weights (i.e., their factors equal 1.0).

In producing regional or national estimates of the metropolitan population, it is also necessary to compensate for the fact that no metropolitan subsample is identified within two states (Maine and Iowa) and one state-group (Mississippi-West Virginia). There were no metropolitan areas sampled in South Dakota-Idaho-New Mexico-Wyoming. Therefore, a different factor for regional and national estimates is in the right-hand column of Table 4. The results of regional and national tabulations of the metropolitan population will be biased slightly. However, less than one-half of one percent of the metropolitan population is not represented.

Producing Estimates for the Nonmetropolitan Population. State, regional, and national estimates of the nonmetropolitan population cannot be computed directly, except for the 15 states where the factor in Table 4 is 1.0. In all other states, the cases identified as not in the metropolitan subsample (METRO = 2) are a mixture of nonmetropolitan and metropolitan households. Only an indirect method of estimates is available: First compute an estimate for the total population, then subtract the estimate for the metropolitan population. The results of these tabulations will be slightly biased.

Reliability of the Estimates

SIPP estimates in this report are based on a sample; they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same questionnaire, instructions, and enumerators. There are two types of errors possible in an estimate based on a sample survey: nonsampling and sampling. We are able to provide estimates of the magnitude of SIPP sampling error, but this is not true of nonsampling error. Found below are descriptions of sources of SIPP nonsampling error, followed by a discussion of sampling error, its estimation, and its use in data analysis.

Nonsampling Variability. Nonsampling errors can be attributed to many sources, e.g., inability to obtain information about all cases in the sample, definitional difficulties, differences in the interpretation of questions, inability or unwillingness on the part of the respondents to provide correct information, inability to recall information, errors made in collection such as in recording or coding the data, errors made in processing the data, errors made in estimating values for missing data, biases resulting from the differing recall periods caused by the rotation pattern used, and failure to represent all units within the sample (undercoverage). Quality control and edit procedures were used to reduce errors made by respondents, coders, and interviewers.

Undercoverage in SIPP results from missed living quarters and missed persons within sample households. It is known that undercoverage varies with age, race, and sex. Generally, undercoverage is larger for males than for females and larger for blacks than for nonblacks. Ratio estimation to independent age-race-sex population controls partially corrects for the bias due to survey undercoverage. However, biases exist in the estimates to the extent that persons in missed households or missed persons in interviewed households have different characteristics from those of the interviewed persons in the same age-race-sex group. Further, the independent population controls used have not been adjusted for undercoverage in the decennial census.

The following table summarizes information on household nonresponse for the interview months used to produce this report.

Sample Size, by Month and Interview Status

Month	Household Units Eligible			
	Total	Inter- viewed	Not Inter- viewed	Non-Response Rate
Jan 1986	4,700	3,700	1,000	22
Feb 1986	4,700	3,700	1,000	22
Mar 1986	4,800	3,700	1,100	22

Due to rounding of all numbers at 100, there are some inconsistencies. The percentage was calculated using unrounded numbers.

Some respondents do not respond to some of the questions. Therefore, the overall nonresponse rate for some items, such as income and money-related items is higher than the nonresponse rates in the above table. The Bureau has used complex techniques to adjust the weights for nonresponse, but the success of these techniques in avoiding bias is unknown.

Comparability with other statistics. Caution should be exercised when comparing data from this file with data from other SIPP products or with data from other surveys. The comparability problems are caused by the seasonal patterns for many characteristics and by different nonsampling errors.

The following shortfalls are found in the data from the Marital History and Migration History topical modules. SIPP estimates of the number of marriages occurring in 1983, 1984, and 1985 are about 25% lower than the Vital Statistics numbers for these years. (References: The internal Census Bureau memoranda "Further Analysis of SIPP Wave 8 Data on Marital Events" from O'Connell for the Record, December 18, 1987, and "SIPP Estimates of Number of Persons Marrying Per Year" from Singh to Shapiro; draft.) The SIPP estimated proportion of persons moving from April 1985 to March 1986 of 15.5% was significantly lower than the Current Population Survey (CPS) rate of 17.9%. (Reference: The internal Census Bureau memorandum "SIPP Wave 8 Data on Migration" from DeAre to Norton, January 7, 1988.)

Sampling variability. Standard errors indicate the magnitude of the sampling error. They also partially measure the effect of some nonsampling errors in response and enumeration, but do not measure any systematic biases in the data. The standard errors for the most part measure the variations that occurred by chance because a sample rather than the entire population was surveyed.

The sample estimate and its standard error enable one to construct confidence intervals, ranges that would include the average result of all possible samples with a known probability. For example, if all possible samples were selected, each of these being surveyed under essentially the same conditions and using the same sample design, and if an estimate and its standard error were calculated from each sample, then approximately 90 percent of the intervals from 1.6 standard errors below the estimate to 1.6 standard errors above the estimate would include the average result of all possible samples.

The average estimate derived from all possible samples is or is not contained in any particular computed interval. However, for a particular sample, one can say with a specified confidence that the average estimate derived from all possible samples is included in the confidence interval.

Hypothesis Testing. Standard errors may also be used for hypothesis testing, a procedure for distinguishing between population parameters using sample estimates. The most common types of hypotheses tested are: 1) The population parameters are identical versus 2) they are different. Tests may be performed at various levels of

significance, where a level of significance is the probability of concluding that the parameters are different when, in fact, they are identical.

To perform the most common test, let X_A and X_B be sample estimates of two parameters of interest. A subsequent section explains how to derive a standard error on the difference $X_A - X_B$. Let that standard error be s_{DIFF} . Compute the ratio $R = (X_A - X_B) / s_{DIFF}$. If this ratio is between -1.6 and +1.6, no conclusion about the parameters is justified at the 10 percent significance level. If, on the other hand, this ratio is smaller than -1.6 or larger than +1.6, the observed difference is significant at the 10 percent level. In this event, it is commonly accepted practice to say that the parameters are different. Of course, sometimes this conclusion will be wrong. When the parameters are, in fact, the same, there is a 10 percent chance of concluding that they are different.

Note when using small estimates. Because of the large standard errors involved, there is little chance that estimates will reveal useful information when computed on a base smaller than 200,000. Nonsampling error can occasionally occur in one of the small number of cases used in the estimate, causing large relative error in that particular estimate. Also, care must be taken in the interpretation of small differences. Even a small amount of nonsampling error can cause a borderline difference to appear significant or not, thus distorting a seemingly valid hypothesis test.

Standard Error Parameters and Tables and Their Use. To derive standard errors that would be applicable to a wide variety of statistics and could be prepared at a moderate cost, a number of approximations were required. All statistics do not have the same variance behavior; statistics with similar variance behavior were grouped together. Most of the SIPP statistics have greater variance than those obtained through a simple random sample because clusters of living quarters are sampled for SIPP. Two parameters (denoted "a" and "b") were developed to quantify these increases in variance. These "a" and "b" parameters are used in estimating standard errors of survey estimates. The "a" and "b" parameters vary by type of estimate and by subgroup to which the estimate applies. Table 3 provides base "a" and "b" parameters for various subgroups and types of estimates. For SIPP wave 8 core and topical module characteristics, factors for each of the single reference months, September 1985 through February 1986, are provided. The factor multiplied by the base parameters for a given subgroup and type of estimate gives the "a" and "b" parameters for that subgroup and estimate type in the chosen time period. For example, the base "a" and "b" parameters for total income of households are -0.0001274 and 11,013, respectively. The factor for September 1985 is 4, so that "a" and "b" parameters for total household income in September 1985 are -0.0005096 and 44,052, respectively.

The "a" and "b" parameters may be used directly to calculate the standard error for estimated numbers and percentages. Because the actual variance behavior was not identical for all statistics within a group, the standard errors computed from these parameters provide an indication of the order of magnitude of the standard error for any specific statistic. Methods for using these parameters for direct computation of standard errors are given in the following sections.

The user can create far more types of estimates than standard errors are provided for here. Procedures for calculating standard errors for the types of estimates most commonly used are described below. Note specifically that these procedures apply only to reference month estimates or averages of reference month estimates. Refer to the section "Use of Weights" for a detailed discussion of construction of estimates.

Stratum codes and half sample codes are included on the tape to enable the user to compute the variances directly from the data by methods such as balanced repeated replications (BRR). William G. Cochran provides a list of references discussing the application of this technique.¹

1. Sampling Techniques, 3rd Ed., New York: John Wiley and Sons, 1977, p. 321.

Standard errors of estimated numbers. The approximate standard error of an estimated number can be obtained by using formula (1).

$$s_x = ax^2 + bx \quad (1)$$

Here x is the size of the estimate and "a" and "b" are the parameters associated with the particular type of characteristic for the appropriate reference period. Note that this method should not be applied to dollar values.

Illustration of the computation of the standard error of an estimated number. Suppose that SIPP estimates for October 1985 show that there were 472,000 HHs outside metropolitan areas with monthly household income above \$6,000. Then the appropriate "a" and "b" parameters and factor to use in calculating a standard error for the estimate are obtained from Table 3. They are $a = -0.0001274$, $b = 11,013$ and a factor of 2 for October.

Using formula (1), the approximate standard error is

$$(-0.0002548)(472,000)^2 + (22,026)(472,000) = 102,000$$

The 90-percent confidence interval as shown by the data is from 308,800 to 635,200. Therefore, a conclusion that the average estimate derived from all possible samples lies within a range computed in this way would be correct for roughly 90 percent of all samples.

Standard errors of estimated percentages. This section refers to percentages of a group of persons, families, or households possessing a particular attribute.

The reliability of an estimated percentage, computed using sample data for both numerator and denominator, depends upon both the size of the percentage and the size of the total upon which the percentage is based. Estimated percentages are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more, e.g., the percent of people employed is more reliable than the estimated number of people employed. When the numerator and denominator of the percentage have different parameters, use the parameters for the numerator. The approximate standard error, $s_{x,p}$, of the estimated percentage p can be obtained by the formula

$$s_{x,p} = \frac{b}{x} p(100-p) \quad (2)$$

Here x is the size of the subclass of households or persons in households which is the base of the percentage, p is the percentage ($0 < p < 100$), and b is the "b" parameter for the numerator.

Illustration of the computation of the standard error of an estimated percentage. Suppose that, in November, of the 16,812,000 persons in nonfarm households with a mean monthly household cash income of \$4,000 to \$4,999, 6.7 percent were Black. Using formula (2) and the "b" parameter of 11,990 and a factor of 1.3333 for November from Table 3, the approximate standard error is

$$\frac{(15,986)}{(16,812,000)} (6.7) (100-6.7) = 0.8 \text{ percent}$$

Consequently, the 90-percent confidence interval as shown by these data is from 5.4 to 8.0 percent.

Standard error of a difference. The standard error of a difference between two sample estimates is approximately equal to

$$s_{(x-y)} = s_x^2 + s_y^2 \quad (3)$$

where s_x and s_y are the standard errors of the estimates x and y . The estimates can be numbers, percents, ratios, etc. The above formula assumes that the sample correlation coefficient, r , between the two estimates is zero. If r is really positive (negative), then this assumption will lead to overestimates (underestimates) of the true standard error.

Illustration of the computation of the standard error of a difference. Suppose that SIPP estimates show the number of persons age 35-44 years in nonfarm households with mean monthly household cash income of \$4,000 to \$4,999 during the fourth quarter of 1985 was 3,186,000 and the number of persons age 25-34 years in nonfarm households with mean monthly household cash income of \$4,000 to \$4,999 in the same time period was 2,619,000. The standard errors of these numbers are 208,000 and 189,000, respectively. Assuming that these two estimates are not correlated, the standard error of the estimated difference of 567,000 is

$$(208,000)^2 + (189,000)^2 = 281,000$$

Suppose that it is desired to test at the 10 percent significance level whether the number of persons with mean monthly household cash income of \$4,000 to \$4,999 during the third quarter of 1985, (X), was different for persons age 35-44 years in nonfarm households than for persons age 25-34 years in nonfarm households. The difference, $X_{35-44} - X_{25-34}$ is 567,000. The difference divided by the standard error of the difference, $(X_{35-44} - X_{25-34})/s_{DIFF}$ is 2.02. Since the ratio is greater than 1.6, the data show that the difference between the two age groups is significant at the 10 percent level.

Standard error of a mean. A mean is defined here to be the average quantity of some item (other than persons, families, or households) per person, family, or household. For example, it could be the average monthly household income of females age 25 to 34. The standard error of a mean can be approximated by formula (4) below. Because of the approximations used in developing formula (4), an estimate of the standard error of the mean obtained from that formula will generally underestimate the true standard error. The formula used to estimate the standard error of a mean x is

$$s_x = \frac{b}{y} s^2 \quad (4)$$

where y is the size of the base, s^2 is the estimated population variance of the item and b is the parameter associated with the particular type of item.

The estimated population variance, s^2 , is given by formula (5):

$$s^2 = \sum_{i=1}^c p_i x_i^2 - x^2 \quad (5)$$

where it is assumed that each person or other unit was placed in one of c groups; p_i is the estimated proportion of group i ; $x_i = (Z_{i-1} + Z_i)/2$ where Z_{i-1} and Z_i are the lower and upper interval boundaries, respectively, for

group i . The estimate x_i is assumed to be the most representative value for the characteristic of interest in group i . If group c is open-ended, i.e., no upper interval boundary exists, then an approximate value for x_c is

$$x_c = \frac{3}{2} Z_{c-1} \quad (6)$$

Illustration of the Computation of the Standard Error of an Estimated Mean. Suppose that the average of monthly household incomes during the fourth quarter 1985 of persons age 25 to 34 are given in the following table.

Table 2. Distribution of Monthly Household Income Among Persons 25 To 34 Years Old.

Total	Under \$300	\$300 to \$599	\$600 to \$899	\$900 to \$1,199	\$1,200 to \$1,499	\$1,500 to \$1,999	\$2,000 to \$2,499	\$2,500 to \$2,999	\$3,000 to \$3,499	\$3,500 to \$3,999	\$4,000 to \$4,999	\$5,000 to \$5,999	\$6,000 and over

Using formula (5) and the mean monthly household cash income of \$2,530 the approximate population variance, s^2 , is

$$s^2 = \frac{1,371}{39,851} (150)^2 + \frac{1,651}{39,851} (450)^2 + \dots + \frac{1,493}{39,851} (9,000)^2 - (2,530)^2$$

$$= 3,159,887.$$

Using formula (4), an appropriate "b" parameter of 8912 from Table 3 and the factor 1.5555 for the fourth quarter of 1985, the estimated standard error of a mean x is

$$s_{\bar{x}} = \frac{13,863}{39,851,000} (3,159,887) = \$33$$

Standard error of a median. The median quantity of some items such as income for a given group of persons, families, or households is that quantity such that at least half the group have as much or more and at least half the group have as much or less. The sampling variability of an estimated median depends upon the form of the distribution of the item as well as the size of the group. An approximate method for measuring the reliability of an estimated median is to determine a confidence interval about it. (See the section on sampling variability for a general discussion of confidence intervals.) The following procedure may be used to estimate the 68 percent confidence limits and hence the standard error of a median based on sample data.

1. Determine, using formula (2), the standard error of an estimate of 50 percent of the group;
2. Add to and subtract from 50 percent the standard error determined in step (1);
3. Using the distribution of the item within the group, calculate the quantity of the item such that the percent of the group owning more is equal to the smaller percentage found in step (2). This quantity will be the upper limit for the 68 percent confidence interval. In a similar fashion, calculate the quantity of the item

such that the percent of the group owning more is equal to the larger percentage found in step (2). This quantity will be the lower limit for the 68 percent confidence interval;

4. Divide the difference between the two quantities determined in step (3) by two to obtain the standard error of the median.

To perform step (3), it will be necessary to interpolate. Different methods of interpolation may be used. The most common are simple linear interpolation and Pareto interpolation. The appropriateness of the method depends on the form of the distribution around the median. We recommend Pareto interpolation in most instances. Interpolation is used as follows. The quantity of the item such that "p" percent own more is

$$X_{pN} = \exp \frac{\text{Ln} (pN/N_1)}{\text{Ln} (N_2/N_1)} \text{Ln} (A_2/A_1) A_1 \quad (7)$$

if Pareto interpolation is indicated and

$$X_{pN} = \frac{pN - N_1}{N_2 - N_1} (A_2 - A_1) + A_1 \quad (8)$$

if linear interpolation is indicated, where

- N is size of the group,
- A₁ and A₂ are the lower and upper bounds, respectively, of the interval in which X_{pN} falls,
- N₁ and N₂ are the estimated number of group members owning more than A₁ and A₂, respectively,
- exp refers to the exponential function, and
- Ln refers to the natural logarithm function.

It should be noted that a mathematically equivalent result is obtained by using common logarithms (base 10) and antilogarithms.

Illustration of the Computation of a Confidence Interval and the Standard Error for a Median. To illustrate the calculations for the sampling error on a median, we return to the same example used to illustrate the standard error of a mean. The median monthly income for this group is \$2,158. The size of the group is 39,851,000.

1. Using formula (2), the standard error of 50 percent on a base of 39,851,000 is about 0.9 percentage points.
2. Following step (2), the two percentages of interest are 49.1 and 50.9.
3. By examining Table 2, we see that the percentage 49.1 falls in the income interval from \$2,000 to \$2,499. (Since 55.5 percent receive more than \$1,999 per month, but only 40.9 percent receive more than \$2,499 per month, the quantity that exactly 49.1 percent receive more than must be between \$2,000 and \$2,499.) Thus A₁ = \$2,000, A₂ = \$2,500, N₁ = 22,106,000, and N₂ = 16,307,000. Implementing Pareto interpolation, the upper bound of a 68 percent confidence interval for the median is

$$\exp \frac{\text{Ln} (.491) (39,851,000)}{\text{Ln} \frac{22,106,000}{16,307,000}} \text{Ln} \frac{2,500}{2,000} \$2,000 = \$2,187$$

Also by examining Table 2, we see that the percentage 50.9 falls in the same income interval. Thus, A_1 , A_2 , N_1 , and N_2 are the same. So the lower bound of a 68 percent confidence interval for the median is

$$\exp \frac{\frac{\ln (.509) (39,851,000)}{22,106,000}}{\frac{\ln 16,307,000}{22,106,000}} \ln \frac{2,500}{2,000} \quad \$2,000 \quad = \quad \$2,130$$

Thus, the 68 percent confidence interval on the estimated median is from \$2,130 to \$2,187. An approximate standard error is

$$\frac{\$2,187 - \$2,130}{2} = \$29.$$

Using linear interpolation, the 68 percent confidence interval of the estimated median is \$2,157 to \$2,219 and the approximate standard error is \$31.

Standard errors of ratios of means and medians. The standard error for a ratio of means or medians is approximated by formula (9):

$$s_{\frac{x}{y}} = \frac{s_x}{y} \sqrt{\frac{x^2}{y^2} + \frac{s_y^2}{y^2}} + \frac{s_x}{x} \sqrt{\frac{s_x^2}{x^2}} \quad (9)$$

where x and y are the means or medians, and s_x and s_y are their associated standard errors. Formula (9) assumes that the means or medians are not correlated. If the correlation between the two means or medians is actually positive (negative), then this procedure will provide an overestimate (underestimate) of the standard error for the ratio of means and medians.

APPENDIX D

EVALUATION OF SIPP WAVE 8 CORE AND TOPICAL MODULE

Fertility History Data

SIPP Wave 8, 1984 Panel data on fertility and work history during the women's first pregnancy appear to be of reasonable quality both in terms of trends of reported events and levels of fertility. Data on birth expectations, however, appear to suffer from unusually high noninterview rates owing to the "respondent only" format of the question; these data should not be used by analysts as the nonresponse problem for this series of items is beyond all reasonable standards of acceptance.

The Items

Children ever born. For the first time on a Census Bureau survey, men were asked about the number of children they had ever fathered. Nonresponse rates were very low (5-6 percent) for persons 25 and over and only slightly higher than females for persons under age 25 (Table 1). Rates of children ever born and parity distributions for men, by age, were also comparable, as one would expect, to females in the previous age group (men usually marry women a few years younger than themselves). Fertility data derived from the SIPP were also comparable in levels and distributions to CPS data and were within margins of sampling error. SIPP children ever born data, in summary, are quite acceptable for the analyst to use and appear to adequately characterize the current fertility status of both men and women.

First births. Cumulative proportions of women ever having a first birth, by the woman's year of birth, are shown in Table 2. Again, SIPP data approximate similarly derived CPS data and provide cumulative fertility rates well within sampling variation.

Table 3 further examines the timing of the first birth among women from the CPS and the SIPP module in addition to official reports from Vital Statistics records. Despite apparent differences in either numbers of first births occurring in different time periods or estimates of the level of out-of-wedlock conceptions, all of the SIPP data are within the sampling variation of the survey and are acceptable. (The 41-percent level for 1985 has a 90-percent confidence level of ± 9 points.) SIPP data on out-of-wedlock childbearing are probably as good as we can expect from any survey of comparable complexity and sample size.

Last births. SIPP fertility history data concerning the dating of the last birth also prove very accurate as shown in Table 4. The remarkable estimate of births in 1985 from SIPP and the associated distributions are right on target with official Vital Statistics tabulations. No more needs to be said about this point.

Imputation rates for first and last births. A principal reason for the highly accurate reporting of fertility events in SIPP can be attributed to the direct transcription of birth dates for children (if all the woman's children were currently living with her in the household) from the control card to the questionnaire. Of the 8,425 female respondents reporting that they had ever had a child, 3,324 had their children's birth dates directly transcribed to the questionnaire. The remaining 5,101 women were asked the dates of birth of their children. First birth dates were imputed for 887 children; of the remaining 4,263 women with 2 or more births, 560 women had the date of their second child's birth imputed. Given the complexity of the survey and its length, these imputation rates are well within one's expectations.

Employment history around the first birth. Comparative statistics on employment history during and before the first pregnancy are few. SIPP employment history data appear to be well answered (Table 5) with imputation rates in the 8- to 9-percent range, with the exception of the extremely high imputation rates for the reentry dates after the woman's first birth (33 percent). Caution should be used, of course, when using any of these estimates.

Work history data shown in Table 6 indicate a progression of increasing labor force participation both before first birth and during first pregnancy since 1960, as expected. Comparative data for "ever-married" women 15-to-44-years old whose first birth occurred in 1970-73 (from the 1973 National Survey of Family Growth) indicate that 61 percent worked during their first pregnancy compared to 52 percent among SIPP women.

Table 7 also shows an increasing proportion of women who worked longer into their first pregnancy since 1960. Again, the data seem reasonable and intuitively logical. Unfortunately, these apparently useful and reliable data were subsequently dropped from the SIPP fertility module and are not scheduled to appear after Wave 4 of the 1985 Panel.

Birth expectations. Very high noninterview rates make these questions not worth analyzing. Apparently, SIPP is not the vehicle to use for questions which are answerable only by the respondent in question (i.e., no proxy answers). These questions, will not be asked past Wave 4 of the 1985 Panel.

Household Relationship Data

These data provide uniquely detailed information for the U. S. about the specific family and nonfamily relationships that link each household member to every other member of his/her household. Since the data collection procedures involve explicitly asking the respondent about each family/nonfamily relationship within the household, and since a flashcard listing each possible response category is provided to aid the respondent in answering, the responses provided are not only more detailed than relationship data collected on the control card, they also may be more accurate. Because the new data are uniquely detailed, and because of the need to release the data in a timely fashion, at the outset a two-stage strategy for developing edit procedures was adopted. The first stage, which has been implemented with these data, makes the fewest possible changes in reported data that are required to insure consistency with only four variables from the control card which are known to be of extremely high quality: (1) age, (2) sex, (3) parent line number, and (4) spouse line number. The second step, to be implemented when resources permit, will involve further research to develop extensions and refinements of first-stage procedures. The second-stage procedures will mainly be directed toward locating "unknowns" to appropriate categories. The evaluation of current data, which follows, indicates that current data based on first-stage edit procedures are of good quality since current results correspond closely to pertinent results obtained from other sources.

First, the total allocation rate of 9.8 percent consists of three components: (1) 35 percent for allocations to "parent-child relationship, type unknown," where the designation parent-child is correct but the type of relationship (natural, step, adopted, foster) is unknown; (2) 3.6 percent for allocations to "relationship unknown"; and (3) 2.8 percent for all allocations of all other kinds. Since the entire allocation process is based only on changes which insure consistency with four variables known to be of extremely high quality (age, sex, parent line number, and spouse line number), and since the total allocation rate of 9.8 percent falls near the median value of allocation rates for all variables in the decennial census in 1980, the size of the allocation rate is not a cause for concern. As indicated on other occasions, the edit procedures developed for this round of data represent the first stage in a two-stage process. The potential gain to be derived from implementing, when resources permit, the second-stage – the extension and refinement of first-stage edit procedures – is reflected mainly in the 3.6 percent of the cases in which the relationship is unknown and the 3.5 percent of cases in which the precise type of parent-child relationship is unknown. Although more fully edited data are potentially valuable, nothing about current allocation rates undermines our confidence in the data from Wave 8.

Second, the overall distribution of relationships in column 1 of the matrix is close to the distribution of corresponding results from the 1980 census (selected for comparison because of the relatively detailed relationship data which it provides). The results for SIPP and the census are, respectively: (1) spouse, 33.5 percent vs. 34.7 percent; (2) child, 53.1 percent vs. 54.2 percent; (3) grandchild, 2.4 percent vs. 1.9 percent; (4) parent, 2.1 percent vs. 0.9 percent; (5) child-in-law, 0.4 percent vs. 0.3 percent; (6) sibling, 1.3 percent vs. 1.4 percent; (7) other relative, 2.2 percent vs. 1.9 percent; (8) nonrelative, 3.7 percent vs. 4.2 percent; and (9) unknowns, 1.3 percent vs. 0.0 percent. The small differences between the specific categories range from 0.1 to 1.2 percentage points, and the 1.3 percent for unknowns is close to the allocation rate of 1.1 percent for

relationship in the 1980 census. Since these measured differences may be partly due to the fact that the SIPP data are unweighted counts, from the perspective of data quality the differences must be judged small.

Third, the distribution of sons/daughters (and fathers/mothers, since each parent-child relationship in the household is identified only once) by type of relationship is similar to the distribution of sons/daughters by type as recently estimated using the marital and fertility histories of the June 1980 CPS. The results from SIPP (for all persons) and from the CPS (for persons age 0-17) are, respectively: (1) natural child, 86.6 percent vs. 91.7 percent; (2) stepchild, 4.2 percent vs. 5.6 percent; (3) adopted child, 1.7 percent vs. 2.5 percent; (4) foster child, 0.4 percent vs. 0.4 percent; and (5) unknown, 6.9 percent vs. 0.2 percent. The differences for categories other than "unknown" range from 0.0 to 5.1 percentage points. Furthermore, since each of the values for meaningful categories from SIPP is below the corresponding value from the CPS, if the unknowns were allocated to meaningful categories, the SIPP results would approach more closely the CPS results. For example, if the distribution of "unknowns" were the same as the distribution of "knowns," then the SIPP and CPS results would be, respectively: (1) natural child, 93.2 percent vs. 91.7 percent; (2) stepchild, 4.5 percent vs. 5.6 percent; (3) adopted child, 1.8 percent vs. 2.5 percent; and (4) foster child, 0.4 percent vs. 0.4 percent. These differences fall within the narrow range of 0.0 to 1.5 percentage points. By either accounting, the differences must be judged small since the SIPP data are unweighted, and since the SIPP data pertain to all persons while the CPS data pertain to persons age 0-17.

Fourth, the distribution of relationships by sex in column 1 of the matrix are generally similar to the distribution of relationships to householder by sex for the 1980 census. The proportion male for SIPP and the census are, respectively: (1) child, 51.5 percent vs. 52.4 percent; (2) sibling, 53.3 percent vs. 47.4 percent; (3) grandchild, 53.4 percent vs. 52.3 percent; (4) spouse, 11.0 percent vs. 3.7 percent; (5) parent, 30.4 percent vs. 21.1 percent; and (6) child-in-law, 51.3 percent vs. 52.2 percent. Three differences fall within the narrow range of 0.9 to 1.3 percentage points. The differences of 5.9 to 9.3 percentage points for sibling, spouse, and parent may be due to one or a combination of factors. For the category "spouse," most of the difference is probably due to the fact that in SIPP a much larger proportion of householders in married-couple households is female than is true in the census. For the categories "sibling" and "parent," some of the explanation may lie in the small sizes, 246 for siblings and 250 for parents. In addition, some of the difference for all the categories may result from the fact that the person in column 1 of the matrix is not necessarily the householder in SIPP, and the fact that SIPP counts are unweighted. In view of these legitimate and/or artifactual sources of possible difference, the magnitude of these measured differences must be judged small.

Summary. Overall, the data appear to be of good quality. The nature and magnitude of the allocation rate is such that it provides no cause for concern. As indicated on other occasions, the edit procedures developed for this round of data represent the first stage in a two-stage process. The first stage has been implemented, and it yields excellent data, since the data as currently edited correspond closely to pertinent estimates from other data sources. The results for Wave 8, however, also suggest that the next stage (the extension and refinement of current edit procedures) should be undertaken when resources permit, mainly to provide the basis (1) for allocating the 3.5 percent of the cases where the precise type of parent-child relationship is unknown and the 3.6 percent of cases where the general type of relationship is unknown, and (2) for insuring that data now consistent in terms of basic nuclear family relationships are consistent for all possible sets of three or more persons in the household. Despite the potential value of further refinements, the evaluation indicates that the quality of the SIPP family/household relationship data for Wave 8 is good.

Number of Persons Marrying Per Years

Table 11 shows SIPP estimates of number of marriages occurring within given years. Because differences between SIPP and Vital Statistics estimates for 1983, 1984, and 1985 are noticeably larger than for other years, representatives from Population Division (POP) and Statistical Methods Division (SMD) discussed the issue. This note addresses the concern raised by POP that the mover's adjustment used by SIPP is the cause of these larger differences and indicates weighting and procedural areas where further exploration could be done.

After theoretical and intuitive reconsideration of the mover adjustment, it was concluded that it is appropriate to obtain the correct probabilities of persons in the sample at a given time. Theoretically the adjustment will produce unbiased estimates for any subset of the population. (See Huang's 1984 ASA paper entitled "Obtaining Cross-Sectional Estimates from a Longitudinal Survey.") For intuitive purposes, assume that 250 100-level mover persons who marry in a given year are male and 250 are female. Further assume that each of these move in with only one other person (this person is a 200+-level person) and that the baseweight of each 100-level person is w before moving and $(1/2)w$ after moving. Corresponding weights for the 200+-level persons marrying 100-level movers are 0 and $(1/2)w$. The estimated number of mover marriages is the weighted number of 100-level male movers who marry plus the weighted number of 200+-level males who marry 100-level female movers. Thus, using unadjusted baseweights, the estimated number of such marriages is $250w$ (i.e. $250(w) + 250(0)$). (This is the approach of the Panel Survey of Income Dynamics (PSID) when the estimates are formed with individual weights.) Using mover adjusted baseweights, the estimate is also $250w$ (i.e. $250(1/2)w + 250(1/2)w$). Additionally, if mover's weights were a problem, mover's weights would have little affect on number of calendar year 1983 marriages since very few movers contribute to this estimate and the differences would increase as the panel ages. However, as shown by Table 9, differences in SIPP and Vital Statistics estimates for 1983 are large when compared to similar differences for earlier years and are similar to differences for 1984 and 1985. Further, the differences are not increasing as the panel ages. Thus, the methodology used to obtain SIPP base weights (which include the mover's adjustment) is sound.

If the primary objective of SIPP is to make estimates of the type examined, the mover's weight adjustment will be the same. However, we may want to explore the use of a different set of noninterview cells than is currently used in the weighting process, as well as including different or additional variables in the second-stage adjustment. Attention, though, should not simply focus on weighting. From Table 10, it is clear that fewer 100-level persons were reported as marrying in a given year after 1982 than before. This strange drop suggests the possibility of nonreporting, nonresponse, or processing errors and raises questions about the overall procedures to capture this information. (e.g.: Are persons soon to be married being interviewed at Wave 1? Is control card item 26a being filled or updated correctly before check item T6 of the 1984 Panel Wave 8 questionnaire is filled by the enumerator? Are newly married persons being followed?, etc.)

In summary, movers weights are not responsible for the observed differences. A revision to the noninterview or second-stage adjustment procedures may improve estimates to some extent. However, research should be done in other areas as well.

Marital Events

More tabulations concerning the shortfall in marriages during the life of the SIPP 1984 Panel were prepared. It appears that the smaller counts of 1983 marriages results from a shortfall in the numbers of respondents answering that they were married in 1983 as compared to 1982 and previous years (Table 11). We cannot as yet explain the lack of enthusiasm for reporting 1983 as a marriage year as imputations are very minimal for the entire decade of the 1980's (Table 12). Imputations are higher for previous decades but as indicated previously, the estimates of marriages for past years were comparable to Vital Statistics data.

For 1984 and 1985, the weighting problem appears to be more culpable. Data in Table 11 show that 30 to 50 percent of all persons in the sample in Wave 8 who reported marrying in 1984 or 1985 were 200-level persons, i.e., they entered after the panel began. As such, since the 200-level persons have substantially lower rates, they weight the marriages down in 1984-85. They also weight them down in prior years, but before 1983 they make up only about 5 percent of all persons marrying in these years.

In addition, 1984-85 data have another "bonus" thrown in – the 100-level persons who also married in these years (unlike those who married in prior years), also have lower weights (Table 13) as their newly acquired spouse absconded with part of their own weight!

Marital History Data

The problem of SIPP results yielding lower absolute levels for recent marriages than Vital Statistics (see Table 9) remains to be solved. Similarly, the SIPP results when compared with June 1985, CPS marital history results show SIPP to over-represent, by about 20 percent, the evermarried population at ages 20-30 and underrepresent, by about 15 percent, the ever-married population at ages 60 and above (for ages 30-60, the two surveys are close). The higher estimates from SIPP of young evermarried people (26 million in SIPP vs. 21.2 million in CPS) are consistent with higher rates of attrition for young never-married people. The lower SIPP estimates of older evermarried people (31.6 million in SIPP vs. 36 million in CPS) is a puzzle.

The allocation rates for most marital history categories are generally higher in SIPP than in CPS, but insofar as we can determine, the rates are roughly comparable (see Table 19). Not surprisingly, the allocation rates for self-respondents were much lower than for proxy circumstances. Overall, the allocation rates for marital history are higher than for most other variables.

Apart from the findings discussed above, the SIPP marital history results compare favorably with the June 1985 CPS marital history results (see Table 20). Median age at marriage for various birth cohorts from each survey was calculated, and the estimates were quite similar. Also, cross-survey comparisons of distributions by times married and incidence of divorce according to times married show close agreement.

Migration

In the process of checking the data from the Migration History module, a shortfall in the number of recent migrants has been found and a resultant underestimate of the mobility rate of the population. The number of persons 15 years of age and older who changed residence between April 1985 and March 1986 was 28,580,000 according to the SIPP, about 4.5 million lower than the CPS estimate of 33,070,000 (see Table 14). The estimated mobility rate (proportion of persons moving) for 1985-86 was just 15.5 percent, lower than any rate recorded in the CPS in the last 40 years.

When interpreting these comparisons and the ones that follow, bear in mind the impact of differences between the surveys. For example, because of differences in survey design, the SIPP estimate of movers from abroad are expected to be lower. Additionally, because of the attrition of SIPP movers by Wave 8, we'd expect SIPP estimates of recent movers to be lower.

A few characteristics of recent movers available from both CPS and SIPP data sources were compared. SIPP estimates had 2.8 million fewer men and 1.7 million fewer women than the corresponding CPS estimates (Table 16). For both sexes, the greatest differences were in ages 20-29 and 35-44. These age groups accounted for 3.3 million of the 4.5 million shortfall (men, 2.1 million; women, 1.3 million).

The regional distribution and migration patterns of recent movers were also examined (Table 18). The current distribution of recent movers from the SIPP shows 4 million fewer movers than the CPS in the South and the West. Only the Midwest has a similar estimate of total movers from both data sources. The interregional flows from the SIPP don't really hold up to analysis, given the very small numbers of recent movers in the survey. (Of the total 12 flows between the 4 regions, 10 flows are based on unweighted counts of less than 30 persons.) Both the size of the estimated flows and the rank orderings of the flows between regions in the SIPP are different from those in the CPS.

Movers from abroad are also considerably underestimated by the SIPP. Data from the Migration Module dealing with movers should be used with caution. The number of migrants from April 1985 to March 1986 is clearly underestimated. The questions in the module provide information on one previous move as well as the most recent move. An attempt was made to put together estimates of the number of migrants from April 1984 to March 1985 to compare with CPS data. The SIPP estimate of movers was 23.7 million movers, significantly

lower than the CPS estimate of 35.5 million. The comparison is pretty rough, however, because movers who moved from 1984-85 and then moved twice after March 1985 are omitted from the 1984-85 estimate. The module tracks only the two most recent moves.

Support for Nonhousehold Members and Work-Related Expenses

Evaluation of the Wave 8 data has not identified any problems. The attached work sheets show distributions and DK rates based on unweighted data; the data are reasonable.

Also tallied are the weighted counts shown below:

1. Persons making regular payments for the support of someone outside the household (children and others).....5.3 million
2. Mean annual amount paid out for child support.....\$1,707
3. Persons with work-related child care expenses.....5.1 million
 Mean weekly amount.....\$52

The CPS report on child support (P23, No. 148) shows that 3.0 million women report receiving an average of \$2,341 in 1983.

The SIPP report on child care (P70, No.9) shows that 5.5 million working persons paid on average a little over \$40 a week for child care (median was \$38).

Given the somewhat different universes and the existence of sampling error (the standard error of the estimate of \$52 a week was \$6) the data appear to be reasonably consistent.

Approximately 5.3 million persons made support payments for someone living outside of households and the mean annual payment was \$1,707. Take a closer look at how the SIPP data on child support payments compared with the CPS data on receipt of child support payments. The data are shown below:

SIPP

- A. Persons making support payments for children living outside the household...3.4 million
- B. Mean annual amount.....\$2,665

CPS

- A. Persons receiving child support payments.....3.0 million
- B. Mean annual amount.....\$2,341

The conclusion is that the SIPP estimates are reasonable

Analytical Problems Encountered When Using Wave 8 Data for Cross-sectional Analysis

Problems Identified. Cross-sectional analysis of SIPP data involving households which have experienced the addition of persons 15+ to that household (e.g., by marriage, cohabitation, returning older children) during the life of the panel will produce gross underestimates of demographic and economic characteristics.

Background. During the course of reviewing Wave 8, 1984 Panel data on marital history, a tabulation was produced from the retrospective marital history items on the number of men and women marrying each year. The attached table shows the results from the SIPP tabulations and comparative data from official Vital Statistics records on the number of marriages occurring annually for selected years from 1960 to 1985 (SIPP Wave 8 data were collected in January-March 1986).

Although fairly reasonable estimates of annual marriages from SIPP were obtained for the years before 1983, the year the SIPP panel began, data from SIPP for 1983-1985 only obtain marriage levels of 75 percent of the Vital Statistics estimates. This is a rather perplexing observation since retrospective data always yield the best estimates in the years closest to the survey date. The fact that the SIPP data appear poorest during the life of the survey is surprising. An explanation for these results is not available at this time. Hypotheses concerning estimation and procedural issues have arisen; further research to understand these differences will be necessary.
