

Predicting Household Characteristics Using Street View Images

Raphael Nishimura FedCASIC 2019

Outline

- Motivation
- Research question
- Methods
- Potential problems/limitations
- SRO Mapping Application

Motivation

- Screening households to identify eligible sample elements
 - Time consuming
 - Cost intensive
- Increase screening efficiency by oversampling cases likely to be eligible to the study
- Use frame, commercial and paradata variables to create models to predict eligibility
 - National Survey of Family Growth: 15-49 years old
 - Health and Retirement Study: 50+ years old

Research question

 Can we improve the predictive power of our models by including street view image data?

Methods (1)

- Supervised machine learning algorithm (deep learning) to predict household characteristics (eligibility criteria)
 - Usual frame, commercial and paradata variables
 - Street view images
- Training dataset:
 - Previous national survey conducted by SRO
 - n = 46,797 labeled addresses
 - Addresses geocoded by sample vendor (Marketing Systems Group) using linear interpolation

Methods (2)

- Street View Images:
 - Download static street view images using Google
 Maps Street View Image API
 - R package: googleway (google_streetview function)
- Obtain eligibility probability from machine learning algorithm and compare gains/losses of predictive power with current models in validation dataset

Potential problems/Limitations

- Geocoding
- Position of the street view image:
 - Compass heading of the camera
 - Horizontal field of view (zoom)
 - (up or down) Angle of the camera relative to Street View vehicle
- Time of street view image
- Apartment buildings/complexes
- Gated communities

SRO Mapping Application

- SRO needed a mapping tool to assist in assigning/transfering sample cases to interviewers in the field based on their location
- R Shiny application
- https://kambanane.shinyapps.io/SROMapping Tool/

Thank you!
